In support of the contention that numbers of high and medium grade defectives are capable after proper training of taking their place in the world as harmless and partly self-supporting citizens, Miss Darwin quoted extracts from pamphlets by Dr. Fernald, superintendent of the Massachusetts School for the Feeble-minded at Waverley, and recounted the experiences of Dr. Bernstein of the Rome State School. The experience gained at Waverley showed that there was a class of adult defectives for whom permanent institutional treatment was unnecessary, uneconomical, and in some cases not conducive to happiness; these men and women were, however, unable to fend for themselves in the world. What was needed in many cases after the necessary training had been provided was a half-way house between unrestricted liberty and the wholly restricted life of an institution. This would be partly met by the provision of hostels for mentally defective men and women where they would be under detention, but from which they could go out to work by the day.

The CHAIRMAN said he had been very much impressed by a remark made by Sir Leslie Scott to the effect that parents ought to be taught that there was no stigma or disgrace in having mental disorder in their family. He did not think that it would be too much to ask that parents should be educated to the point of recognizing the earlier obvious symptoms of mental disorder so that they could call in medical advice or, what was of equal or greater value, educational advice at the earliest possible moment.

Short addresses were delivered on the work accomplished by occupation centres in their areas by Miss I. M. BRYAN (Portsmouth), Miss ELFRIDA RATHBONE (London), and Mrs. J. COOKE HURLE (Somerset). Miss NINA BOYLE (Mothers' Defence League) considered that insufficient attention had been paid to some of the causes of mental deficiency such as underfeeding. The administration of some institutions for mental defectives called for the sternest criticism.

Mr. A. H. TREVOR (Board of Control) said, in the course of discussion, that a proposal had been laid before the Treasury to allow an increased grant to voluntary associations for the purpose of starting occupation centres. He believed and hoped there would not be much objection to certain amplifications of the grants for this purpose.

PROFESSOR SANARELLI, director of the Institute of Hygiene, has been elected director of the University of Rome.

The second International Congress of Comparative Pathology will be held in Rome on September 20th.

IN-PATIENT TREATMENT OF OPHTHALMIA NEONATORUM IN LONDON.

In 1918 the Metropolitan Asylums Board, at the request of the Ministry of Health, established an institution—St. Margaret's Hospital, Leighton Road, Kentish Town—for the treatment of cases of ophthalmia neonatorum. This hospital, to which certain open-air (balcony) wards were subsequently added, now contains accommodation for sixty cases, including beds for mothers, who are encouraged to accompany their babies, and treatment is available for those mothers who are willing to receive it. The accommodation provided at the hospital has, however, never been fully utilized, except for occasional short periods, and the Board has also experienced a continuous difficulty in securing the admission of babies in the earliest stages of the disease. From time to time various steps have been taken with a view to the more extended use of the hospital, but these have not met with such success as had been hoped for. The Board, therefore, recently convened a conference to discuss the measures which it might be thought could usefully be taken to secure that greater advantage should be taken of the facilities provided by the hospital. This conference took place at the office of the Board on July 19th, 1922, and was attended by the following:

Representatives of the Board.

Mr. Walter Eickhoff, J.P., Chairman of the Board.
Mr. C. Botterill, Chairman of the Infectious Hospitals Committee.
Dr. Lauriston Shaw, Vice-Chairman of the Infectious Hospitals Committee.
Miss M. B. Broadbent, Chairman of the St. Margaret's Hospital Subcommittee.
Dr. F. F. Caiger, Chief Medical Officer, Infectious Hospital Service.
Mr. M. S. Mayon, Ophthalmic Surgeon, St. Margaret's Hospital.
Dr. C. Price, Medical Officer, St. Margaret's Hospital.

Representatives of other Authorities.

Ministry of Health.—Mr. H. O. Stutchbury, Assistant Secretary;
Dr. Janet Campbell, Senior Medical Officer.
London County Council.—Dr. Elizabeth MacRory.
Section of Ophthalmology, Royal Society of Medicine.—Sir John Parsons, C.B.E., F.R.S., Mr. J. B. Lawford, F.R.C.S.
Metropolitan Branch, Society of Medical Officers of Health.—Dr. T. Shadick Higgins, Medical Officer of Health, St. Pancras; Dr. C. Porter, Medical Officer of Health, St. Marylebone (Hon. Sec.).
Local Medical and Panel Committee for London.—Dr. W. Coode Adams and Dr. J. H. Traquair.
Central Midwives Board.—Dr. J. S. Fairbairn and Mr. H. G. Westley, M.A. (Secretary).
Midwives' Institute.—Miss Rosalind Paget and Miss Olive Haydon.

The proceedings were opened by the Chairman of the Board, who presided, and briefly explained the position.

The ophthalmic surgeon attached to the hospital (Mr. Mayon) said that roughly one-third of the cases of ophthalmia neonatorum notified in London were admitted to the hospital, the figures being:—

	1919.	1920.	1921.	1922.*
Number notified ...	870	1185	1076	426
Number admitted ...	281	252	213	115

* To June 17th.

On an average cases were received on the ninth day of the disease, but in other large towns it was about the fifth day. Instances occurred in which cases were not sent to St. Margaret's Hospital until corneal ulceration had developed. The eyes could be saved by appropriate treatment if the cases were received sufficiently early. St. Margaret's Hospital had got the name of a hospital for venereal diseases, and objection had been taken to it by some on that account, but every effort was made at the hospital to avoid any difficulty on this score.

During the general discussion which ensued the work done at St. Margaret's Hospital was referred to in very appreciative terms, and the opinion was expressed that some time must necessarily elapse before the existence of such an institution became generally known in London. It was considered that the percentage of cases notified who were admitted to the hospital was not unsatisfactory, as a large proportion of cases did not need hospital treatment. Emphasis was, however, laid on the desirability of the more prompt notification of cases. It was also stated that many medical students were not adequately instructed in ophthalmology. The objection to the hospital on the ground of its association with the treatment of venereal disease was felt to be one which was very difficult to remove. Further, home duties prevented many mothers from entering the hospital with their infants.

Reference was made from various points of view to the dual control of midwives, who are required to notify the case to the borough medical officer of health where this has not been done by a medical practitioner, and also to inform their local supervising authority, the London County Council, under the regulations, of any emergency (such as the occurrence of ophthalmia neonatorum) in which they had called in medical assistance. It was urged that an institution such as St. Margaret's Hospital was valuable also as affording facilities for the training of midwives, who might, moreover, obtain further experience there after their training as to the best methods of treating ophthalmia neonatorum.

The Board was advised not to seek to extend the method of treating cases of the disease in an institution such as St. Margaret's Hospital until the Departmental Committee on Blindness had submitted its report, as it might be found that there was a better way of dealing with these cases.

THE ADMINISTRATION OF PUBLIC MENTAL HOSPITALS.

REPORT OF THE COMMITTEE OF INQUIRY.

THE Committee of Inquiry into the Administration of Public Mental Hospitals presented its unanimous report to Parliament on July 31st. The Committee, which consisted of Sir Cyril Cobb (chairman), Dr. Percy Smith, and Dr. Bedford Pierce, was appointed by the Ministry of Health in December last to investigate the charges made by Dr. Lomax in his book, *The Experiences of an Asylum Doctor*. It has held twenty-three meetings, and examined thirty-eight witnesses, who included representatives of official bodies, medical superintendents, nurses, members of visiting committees, some independent persons, and seven ex-patients; Dr. Lomax refused to give evidence on the ground that the inquiry should have been by Royal Commission. The report is based on the evidence submitted by these witnesses, on information derived from memoranda, on the results of a questionnaire which was sent to the medical superintendents of twenty-one mental hospitals, and on the Committee's own observations on visiting eight institutions, in six cases without previous announcement.

Dr. Lomax's General Charges.

The Committee points out in its report that Dr. Lomax is not a specialist in mental or nervous disorders; that the experience on which his book is based was derived from his services in one mental hospital extending over a period of nineteen months under war conditions, when, with fourteen mental hospitals closed, there was overcrowding in the others, together with shortage of staff and difficulty regarding food; that many of his statements are based on hearsay evidence or no evidence at all; and that there are gross exaggerations and some statements which are demonstrably untrue. Dr. Lomax attacked what he called the "system," but the Committee points out that there is no "system" in the sense of an arrangement which produces uniform treatment, and therefore no justification for his assumption that what he found in one institution would probably be found in most others, if not in all. The Committee also finds that Dr. Lomax's suggestion that mental hospitals are barrack-like buildings, and that the patients are herded together without classification, is untrue of mental hospitals generally, and grossly exaggerated in the case of Prestwich (on which institution Dr. Lomax based his statements, and where the members of the Committee spent two days in investigation), although the arrangements for the reception of new patients at Prestwich are inadequate.

The Committee is satisfied that there is no ground for the allegation that systematic ill treatment by the staff prevails in mental hospitals (this was not a point very strongly made by Dr. Lomax, but the press gave prominence to sensational statements made by a few witnesses before the Committee). The Committee believes that the public fails to realize the exacting nature of the work which nurses have to do for patients, and the dangerous character of many of their wards. In the two decades before the war there were seventeen instances of one patient's death being caused by another patient, and eight instances of murderous assault upon the superintendents or other medical officers. It is often necessary, therefore, to use considerable force in restraining patients, but, apart from this, there is nothing to justify the allegations of brutal treatment.

Charges Affecting Medical Supervision.

A serious charge made by Dr. Lomax was that sedatives or purgatives were indiscriminately used, and that patients

were kept drugged, and were purged with croton oil as a form of punishment. This charge could be investigated by means of very exact tests obtained from the prescription records of the institutions and from the audited statements of drug purchases. The results of the investigation, taking a period of three years, went entirely to disprove the allegation. At Prestwich Asylum the Committee asked for returns of sedatives administered in one week in 1921 and another week in 1922. The highest number related to a sedative drug, doses of which were given during the week in question to 55 women out of a total of 774 in the institution. The figures for other institutions showed that the administration of sedatives was limited. As for croton oil, this was used at Prestwich, but there was nothing to show that it was used without proper authority. Out of twenty-two institutions furnishing returns fifteen showed that they had not used it at all.

Another allegation referred to the unnecessary detention of patients in institutions. The Committee has discovered no evidence that persons who have recovered their sanity are detained in mental hospitals, but if arrangements for after-care could be improved, and if properly sheltered conditions were available outside, a certain number of patients who did not really need institutional care any longer might be discharged. With regard to the suggestion that no treatment is given, and particularly that there are no facilities for surgical operations, the Committee asks that it may be borne in mind that surgical operations cannot be performed with the same security on the insane as on the sane; but again it finds that there is nothing to show that facilities for surgical treatment are inadequate, or that every effort is not used to restore the insane to health and sanity. Finally, Dr. Lomax referred to the stationary recovery rate. The Committee finds that the recovery rate compares favourably with the recovery rate in general hospitals. One curious fact is that while in one asylum of the most modern construction and equipment the recovery rate is 28.2 per cent., in one of the oldest institutions in the country it is between 33 and 34 per cent. The present recovery rate, even if not improving, is nevertheless very creditable to those who have the care of the mentally afflicted.

The Committee's Recommendations.

Something more positive emerges from the report than the mere disapproving of Dr. Lomax's statements. One of the recommendations is that in future the size of mental hospitals should, as far as possible, be limited to the accommodation necessary for 1,000 persons. In the classification of patients account should be taken of home conditions and surroundings. The superintendent of the mental hospital should be a medical man, with undivided control of the medical and administrative work; and a small advisory committee, preferably associated with the Board of Control, should be available for consultation by visiting committees when making these appointments. The number of assistant medical officers should be increased, and facilities provided for study leave.

Certain other recommendations have to do with the nursing staff. The present rigid system involving short shifts of duty should be discontinued; the hours devoted by each member of the staff to nursing proper should be relatively few, and more time should be given to the nurse's social duties. Other recommendations favour a more varied diet; more attention to the employment of patients, which would be assisted by the appointment at each hospital of an occupations officer; and the strengthening and extension of after-care work. The co-ordination of higher research work by its concentration in a few fully equipped institutions is held to be worthy of consideration.

The opinion is also expressed that the Board of Control needs additional assistance to carry out its work, and that locally it is desirable for visiting committees to be strengthened by the co-option of persons with special qualifications and time to devote to the work, and that some small unofficial committee might be authorized to visit the mental hospitals from time to time. Another matter which has engaged the attention of the Committee is the system under which patients may be visited by their relatives and friends. As far as possible—having regard always to the fact that an insane person may suddenly become violent—friends should be admitted to see the patient actually in the wards, and not in a separate room or corridor. This would go far to disabuse the public mind of the idea that the mental hospital is a place rigidly enclosed and not available to public criticism.

British Medical Journal.

SATURDAY, AUGUST 5TH, 1922.

THE GLASGOW MEETING.

THE reports we were able to publish last week will have told those who were not fortunate enough to be present that the ninetieth Annual Meeting of the British Medical Association was one of the most successful ever held. The attendance was very large, and the whole proceedings were marked with the energy and the air of good-fellowship so noticeable during the last two Annual Meetings at Newcastle and Cambridge. No more appropriate site for a congress of this size could be imagined than the splendid buildings of the University of Glasgow, which provided accommodation for all the scientific Sections, with the Bute Hall as a meeting-place for the Representative Body and the larger social functions. From all three aspects—the scientific and clinical, the political, and the social—the Glasgow meeting of 1922 will long stand out in the annals of the Association. Even the weather, of which great things were not expected, did its best to rise to the occasion.

It is right and fitting that the figure which stands out in the mind of every member who attended this meeting should be that of the President. Had he taken little active part in its proceedings, a medical congress presided over by Sir William Macewen would have gained distinction from his professional eminence and his commanding personality. But the President was the central figure of the week's work and pleasure, and his keen interest in all that went on was an inspiration to every one of the 1,500 members and their many guests. It is no exaggeration to say that Sir William Macewen personified both the spirit and purpose of the meeting and the hospitality of Glasgow. His address at the Glasgow meeting in 1888 was one of the most remarkable contributions to the surgical literature of the time. His presidential address this year on the same subject (with which his name and work will ever be associated) has been described by Sir Frederick Mott as a message to all English-speaking doctors which will be welcomed by them as the last thing said on the subject of brain surgery, and it was informed throughout with the philosophic understanding of a great mind.

The scientific sections, large though their number was, were well attended, and the topics chosen gave occasion for many interesting and profitable debates. We print this week a series of notes of the first day's scientific and clinical proceedings, which will serve to give a brief outline of the papers and discussions. A complete account of the earlier proceedings of the Medico-Sociological Section appears at page 195, and in subsequent issues we shall publish full reports of the work of the other eighteen sections. The afternoon demonstrations, which have become an established feature of the Annual Meetings, were again most successful, while the excellent Pathological Museum, the Public Health Exhibition, and the Trades Exhibition were visited by large numbers.

The publicity given to the proceedings of the Representative Body and of several Sections by the leading Scottish newspapers, and indeed by the lay press at large, was very noticeable. This is an advantage both to the public and to the Association—to the public by making known to it the general aims and methods of the organized medical profession; to the Association because

much of its scientific and professional work is of a kind that flourishes best in contact with well-informed lay opinion. The Annual Meeting serves to remind us all that the chief object of Medicine is the public good. That this is appreciated by responsible newspapers is, we think, shown in the general trend of the comments upon the two principal topics debated by the Representative Body—professional secrecy and hospital policy. Each of these matters abounds in difficulties, but the second is the larger and in some ways the more complex, and a very big part of the Representative Meeting was spent in an attempt to build up an agreed policy within the scaffolding laboriously set up by the Hospitals Committee. A full account of the discussions and conclusions on the hospital question will be found in this and last week's SUPPLEMENT. As we observed last week, it is not surprising that the Association should find great difficulty in exactly defining its position. Briefly put, the outcome of this meeting is that the Council's report and recommendations on the organization of voluntary hospitals were in the main accepted by the requisite majority, and with certain modifications have become the policy of the Association. But there was an evident cleavage of opinion on certain fundamentals, and one important recommendation was taken back for further consideration. We hope in an early issue to discuss more fully the directions in which policy has been modified, and to give some estimate of the practical effect of the decisions reached. Meanwhile we would add a word of praise to the Chairman of the Hospitals Committee for his indefatigable labours in committee, in Council, and in the Representative Body; Ministers piloting a contentious bill through the storms of Westminster might envy him his powers of endurance. Looking back on the four arduous days spent in medico-political business, we may compliment also the Representative Body as a whole, and its chairman, Dr. Wallace Henry, in particular, on completing a stiff course in workmanlike style.

Of the social side of the ninetieth Annual Meeting it should suffice to say that this was under the charge of Scottish hosts, who for months beforehand had spent themselves in perfecting local arrangements. Brief notes of some of the delightful entertainments are printed elsewhere; but it would be impossible to acknowledge all the hospitality offered to members and their families by the medical profession of Glasgow, by the University, and by the civic authorities. In the same way we can only mention a few outstanding names from among the groups of willing workers. The pivot of the whole meeting was the Honorary Local General Secretary, Dr. George A. Allan, whose tireless energy made him ubiquitous. All day and every day he seemed to be at the President's right hand and in a hundred places besides; no one was forgotten and nothing overlooked. Dr. R. A. Hendry was invaluable in dealing with accommodation in hotels and lodgings; this work was under his sole control. Dr. McCutcheon did fine work as transport officer; while Mr. Kay and Dr. F. W. Martin looked after the entertainments in general, with much help from others, notably from Dr. Shannon in the plans for the annual dinner. On the financial side, Professor T. K. Munro and Dr. James H. Martin must be mentioned; also Mr. Harold Yarrow, who acted as treasurer, and Sir John Reid, a member of the executive, who was constant in his attendance and always ready to help. In the organization of the reception room Dr. Allan and his deputy, Mr. James Russell, had valuable aid from Dr. McGregor Robertson. The printing arrangements owed much to Dr. John Patrick and Dr. Cruickshank, the former taking a large share in the production of the *Book of Glasgow* (reviewed by us last week) and,

the latter in the *Handbook* of the meeting. In conclusion, we should like to name all the ladies who helped to make the meeting a success, but this would be invidious, for (as a member from a neighbouring island remarked) the Ladies' Executive worked splendidly to a man.

ANNUAL MEETING NOTES.

THE ERSKINE HOUSE HOSPITAL FOR LIMBLESS AND DISABLED.

PERHAPS not the least interesting of the many excursions organized for the Annual Meeting in Glasgow was that to the Princess Louise Scottish Hospital for Limbless and Disabled Sailors and Soldiers, Erskine House. A large party of ladies and gentlemen who visited Erskine House on the afternoon of July 28th were exceedingly pleased with the work of the hospital and charmed with the beautiful mansion house and surrounding scenery. This institution owes its origin to Sir William Macewen. Very early in the war he recognized that maimed and limbless sailors and soldiers in large numbers would require to be cared for, in regard to provision and repair of artificial limbs, and assisted to render themselves useful citizens by being taught suitable occupations. Sir William Macewen enlisted the sympathies of the citizens of Glasgow, and was supported by an influential committee, which included the Marchioness of Bute, the Marquis and Marchioness of Ailsa, Mrs. Pollock of Ayr, Sir John Reid, Mr. Harold Yarrow, Mrs. McCowan, Miss Anderson, Sir Thomas Dunlop (Lord Provost of the City Glasgow at the time), and many members of the medical profession. Erskine House, formerly the residence of Lord Blantyre, well known in Glasgow and the West of Scotland for his many legal contests with the Clyde Trust, was gifted by Sir John Reid, D.L., Deacon Convener of the Trades' House, for the purpose of the hospital. The mansion is on the left bank of the Clyde, in an estate of 500 acres, a situation in every respect ideal for the purpose. The hospital was ready for patients on October 10th, 1916, and formally opened by Princess Louise on June 6th, 1917. The magnitude of the work may be estimated from figures which have been supplied by Sir John Reid, vice-chairman of the committee. The total number of patients fitted with limbs from the opening until the end of May, 1922, was 6,263, and 4,384 limbs were repaired. The amount of subscriptions received up to the present date is £321,014 ls. 7d. The generous public of Glasgow made many contributions to the hospital. The x-ray room, for example, was completely equipped from the proceeds of a matinée performance in the Alhambra Theatre. The *Glasgow Evening News* organized a subscription list amongst its readers, chiefly in small sums; this fund amounted to £17,000. Mr. and Mrs. Morton of Troon presented the beautiful recreation hall, with stage, billiard tables, and cinematographic apparatus, in memory of their son. Many single beds were endowed by many donors and societies.

The hospital is governed by a voluntary committee, at the head of which is the Lord Provost of the City of Glasgow for the time being, and the committee includes most of the ladies and gentlemen already mentioned. The trades which are taught in the Erskine workshops include shoemaking, basketry, tailoring, saddlery, hairdressing, cabinet-making, and rural industries. After completion of training at Erskine many of the men, with the aid of a Government grant, have set up business for themselves in various parts of the country and abroad. A most important part of the work is the manufacture and fitting of artificial limbs and appliances. The furniture and other articles made are sold in the shops of the Erskine Hospital in Glasgow. At the meeting on July 28th the new President of the British Medical Association, Sir William Macewen, described how he was assisted by Messrs. Yarrow in the manufacture of limbs, and told how the drying of the wood, which was obtained from the neighbourhood, was accomplished, and how the workshops of Messrs.

Yarrow's shipbuilding yard turned out parts for artificial limbs as quickly and as efficiently as renowned makers of these limbs. On the same occasion Sir John Reid invited the ladies of the party to inspect the kitchen arrangements, which he assured them (and they proved for themselves) are up to date in every respect, electric cooking and central heating being employed throughout. The thanks of the visiting party were offered to Sir William Macewen and the committee by Mr. Hempson, solicitor to the Association.

UNIVERSITY RECEPTION.

On the evening of July 26th the Principal and Vice-Chancellor, Sir Donald MacAlister, and Lady MacAlister welcomed the guests of the University of Glasgow in the Bute Hall. The hall itself, the Randolph Hall beyond, and the Hunterian Museum were soon well filled; and light and colour—the scarlet of academic robes preponderating—combined with music and the animation of reunion between old and new friends, to present a vivid contrast to the ansterities of the Representative Meeting so lately concluded in the same setting. In the course of the evening the Chairman of Council, seconded by Mr. Harold E. Yarrow, C.B.E., honorary treasurer of the meeting, expressed the Association's appreciation of the generous hospitality offered by the Court of the University, claiming the Vice-Chancellor as arbiter of the destiny of the profession in another place (the General Medical Council). Sir Donald MacAlister's brief reply was warmly received by all present.

CIVIC RECEPTION.

On the afternoon of July 27th the members of the British Medical Association were given a civic welcome in the handsome City Chambers, which occupy one side of George Square. The reception was attended by large numbers, many of whom wore academic dress. In the absence of the Lord Provost and Senior Magistrate, the guests were received in the Satinwood Salon by Bailie James A. Stewart, Acting Chief Magistrate, and a number of his colleagues. Bailie Stewart afterwards extended a formal welcome to the visitors in the Banqueting Hall, and expressed the Lord Provost's regret for his absence. Perhaps nowhere in the Empire, he said, could the British Medical Association meet more appropriately than in Glasgow, where successive generations of illustrious men had made outstanding contributions to the progress of medical and surgical science. The records of the city and its University contained the names of some of the most eminent surgeons and physicians of the world, and Glasgow was proud to think that to-day it still held in its midst men occupying the highest rank in the profession. He felt that it would be unpardonable in a gathering met to do honour to medical men if he omitted to mention the greatest of them all—one who had shed imperishable lustre upon the annals of surgery, who by his discoveries had been the means of saving hundreds of thousands of lives, and who would be regarded by future generations as one of the greatest benefactors of humanity. It would be an everlasting disgrace to the city if the historic Lister ward, with its beneficent associations, were ever demolished or removed. Sir Humphry Rolleston, K.C.B., President of the Royal College of Physicians of London, briefly offered the thanks of the British Medical Association to the civic authorities of Glasgow, adding that not only was Glasgow famed for enterprise in commerce, industry, and education, but also in hygiene. Sir Thomas Oliver, Professor of Medicine in the University of Durham, who associated himself with the expression of thanks, remarked that there were many directions in which medical research could aid the development of commerce, as, for instance, in the conquest of malaria; in such ways fresh opportunities would be given for the expansion of British enterprise. On the motion of Sir William Macewen a vote of thanks was accorded to Bailie Stewart. While the guests were taking tea music was provided by Mr. Meredith-Kay's orchestra in the Banqueting Hall.

THE OFFICIAL RELIGIOUS SERVICE.

The official religious service (Presbyterian) was held in St. Mungo's Cathedral on Tuesday afternoon, when the President, the Chairmen of Council and of Representative Meetings, and a large number of members were present. Prayer was offered by the Very Rev. W. M. Clow, D.D., Principal of the United Free Church College, and the lesson was read by Sir Donald MacAlister, K.C.B., Principal and Vice-Chancellor of the University. The address was delivered by the Rev. James MacGibbon, M.C., D.D., minister of the cathedral, who took his text from the words: "The Son of Man came not to be ministered unto, but to minister, and to give His life a ransom for many" (Matthew xx, 28). The worth of a profession, he said, was determined by its purpose, and the supreme power in the world was personality. In no profession did a practitioner come into closer touch with others than in the profession of medicine, and there was no profession in which purpose and personality were more imperative. Hippocrates, the father of medicine, must ever remain the type of the perfect physician. It was said of him that he was learned, observant, humane, and of overmastering desire that his experience should benefit others, also that he was pure of mind and master of his passions. Such *philanthropeia* must be the motive of all *philotechnia*. The character maintained by Hippocrates was repeated two thousand years later by one much less renowned, whose name and memory were preserved in that cathedral—Peter Lowe, founder of the Faculty of Physicians and Surgeons of Glasgow, who flourished at the end of the sixteenth and beginning of the seventeenth century.

What had been said of religion (continued the preacher) was true also of medicine—it was an art as well as a science, and as such it implied that reason must work with faith, the emotion with the intellect, even as spirit with matter. The presence of many members of the British Medical Association in that house consecrated to the worship of God as revealed in His Son was a virtual acknowledgement that they believed that the ideal of the physician had been given them in Jesus Christ. In Jesus Christ purpose and personality were combined—pure purpose, perseverance in it to the utmost, with a power of personality which was immeasurable. Christ's efforts for the restoration of man were threefold—teaching, healing, suffering. Healing had been a science, more or less, ever since earliest times, but in all its history it had never revealed anything like the character it possessed in the hands of Jesus Christ. In His method of healing Christ had no forerunner and no successor. He used no drug. He performed no operation; of whatever law of healing He made use, it was a law which depended on Himself for its effectiveness. He was, as it were, the embodiment of the health He restored, just as He was the embodiment of the teaching He gave. It was probable that Christ selected expressly the character of the Son of Man in order that it might be clear to all generations that He claimed to act, not in virtue of powers which mankind could not share, but in virtue of powers which man might and should possess and exercise. "He that believeth on Me, the works that I do shall he do also, and greater works than these shall he do." The Greatest was unique, but no monopolist. He wrought to such effect because He was without sin. It had been said that if sin were to cease, suffering would also cease, but sin meant not only suffering, it meant waste of energy. A great consecrated personality was a channel of power. In conclusion the preacher said that what remained to be achieved in the medical profession was far greater than what had hitherto been accomplished. The domain of medicine bristled with Everests yet unscaled. The further conquests which they prayed God would be made, and to which, by God's help, the present Conference would in some measure point the way, would be no less costly than the victories achieved in the past, and those victories were most likely to be gained by those who humbly and resolutely found in Jesus Christ a noble purpose

and a supreme example, and maintained as their continual habit a close fellowship not only with one another, but with Him.

SURGICAL OPERATIONS AND DEMONSTRATIONS.

As in the two previous years, the Surgical Section attended a series of demonstrations on the three afternoons of the meeting from 2.30 till 4. These demonstrations were arranged under the general direction of Mr. R. H. Parry, and most of the surgeons in the hospitals of Glasgow willingly assisted. On Wednesday and Thursday afternoons Sir William Macewen gave demonstrations in the Surgical Laboratory on hernia and on tumours, the latter with illustrated methods of teaching. On the afternoon of Wednesday, July 26th, demonstrations were carried out by surgeons of the Royal Infirmary. Two wards with side rooms attached were, by the courtesy of the superintendent, emptied of their ordinary patients, and all the cases and specimens for demonstration were collected together in groups. Each surgeon demonstrated his own cases, and the visitors circulated round the wards. The cases were of varied interest, including knock-knee, Albee's operation, oesophageal diverticulum, carcinoma of the stomach, congenital deformities. On Thursday afternoon, July 27th, demonstrations were held chiefly in the Royal Hospital for Sick Children, when Dr. Leonard Findlay showed methods of injection of alcohol in treatment of rectal prolapse and venesection of scalp veins in infancy for obtaining blood for Wassermann reaction and for administration of salvarsan. Mr. Alexander MacLennan gave a demonstration on scoliosis with cinematographic illustrations. Mr. Alexander Mitchell showed skiagrams of bone regeneration, and Mr. William Rankin showed various surgical cases. On Friday afternoon, July 28th, demonstrations were held both in the Western Infirmary and in the Victoria Infirmary. In the Western Infirmary Mr. Edington showed results of laparotomy by transverse incision, and Mr. Archibald Young showed cases of Porthes's disease, excision of upper jaw for sarcoma, colostomy, gastrectomy, and laminectomy. Mr. Young showed also a series of cases of fractures treated by operation, and cases of elbow fractures and epiphyseal separation treated by plating, pinning, etc. In the Victoria Infirmary Messrs. Farquhar Maerne and Robert Carslaw showed cases of mobile ascending colon operated on by the method suggested by Mr. George Waugh, and Mr. Waugh himself operated on an actual case. Mr. James Russell showed some orthopaedic cases—infantile paralysis, club-feet, congenital dislocation of hip—and cases of excision of colon for malignant disease.

A new feature was introduced by the Arrangements Committee at this meeting, on the suggestion of Sir William Macewen, who felt that the early morning hours before the meeting of Sections might be utilized. Accordingly, the surgeons of the infirmaries were approached, and nearly all intimated their willingness to perform operations from 8.30 till 10 each morning. These early morning meetings were generally well attended, and appeared to justify the innovation. Sir William Macewen himself led the way, operating on each of the three mornings, his operations being the radical cure of hernia, osteotomy, and mastoid operation; on these mornings also he demonstrated the end-results in cases of cerebral abscess and the end-results of complete removal of the tongue for carcinoma. In addition to the surgeons of the three large infirmaries—Royal, Western, and Victoria—morning operations were performed by the gynaecologists in these infirmaries, in the Royal Maternity and Women's Hospital, and in the Royal Samaritan Hospital for Women.

SATURDAY'S EXCURSIONS AT GLASGOW.

The last day of the Annual Meeting was given over entirely to the enjoyment of whole-day excursions.

Firth of Clyde Excursion.—A party of 400 left the Broomielaw at 9.15 for a sail on the Firth of Clyde. It was only by mutual arrangement with the three railway companies that this was possible, as the last Saturday of July

is the busiest Saturday of the year. The turbine steamer *Duchess of Argyll*, the boat which carried the party, is "the baby" of the Caledonian Steam Packet Company's fleet, and played no mean part in the war; during the time when the submarine warfare was at its worst she conveyed over 300,000 officers and men to and from France without mishap, and in all made 655 trips. Captain McWaughton, who commanded the boat during the whole period of her war service, was in charge. The weather at the start of the trip left something to be desired, but fortunately it cleared up later, and a most enjoyable day was spent. The ship took the party down the Clyde, called at Gourock to take up a few passengers, and then sailed up Loch Striven and Loch Ridden and thence through the Kyles of Bute and round Bute into Rothesay. A party of about 150 left the steamer at Rothesay in order to be present at the ceremony of the presentation by Provost Eben MacMillan of the Freedom of the Royal Burgh of Rothesay to Sir William Macewen, a native of Rothesay. The ceremony took place in the courtyard of Rothesay Castle, and was thoroughly enjoyed by all present. Sir William was accompanied by Lady Macewen and by their three daughters, three sons (Dr. J. A. C. Macewen, Dr. Hugh Macewen, and Dr. William Macewen), and two small grandsons. The steamer meanwhile sailed round the Cumbræ and returned to Rothesay in time to pick up the party after the ceremony was over, after which she proceeded some little distance up Loch Long and thence down to Gourock, where the party disembarked and was conveyed by a special train to Glasgow, arriving at Glasgow about 7 p.m. Music was supplied on the boat by the kind offices of the Caledonian Railway Company. The arrangements for the trip were admirable, and all those present were delighted with the excursion.

Stirling Trip.—Another most enjoyable trip was the Stirling and Bridge of Allan trip. A party left Glasgow by train for Stirling, where motors were provided in order that the company might see the sights in Stirling, Bridge of Allan, and Dunblane. The Provost of Stirling and the Provost of Bridge of Allan attached themselves to the party at Stirling. General Stirling entertained the party at Keir and conducted it over the Castle, the Wallace Monument, and Dunblane Cathedral. A very enjoyable visit was also made to the famous Keir Gardens, and an opportunity was afforded of seeing the mineral wells at Bridge of Allan. The arrangements for the Stirling trip were in the hands of Dr. Hossack Fraser.

Ayr Trip.—Another party left Glasgow by train for Ayr, where motors were provided in order that the places of interest in and around Ayr might be visited. The arrangements for this trip were in the hands of Dr. G. Douglas McRae, President of the Glasgow and West of Scotland Branch, and the President of the Burns Federation, Mr. Dnnan McNaught, LL.D., accompanied the party. Dr. Crerar of Maryport was another who contributed in no small measure to the success of the trip. Tea was kindly provided by the Marquess and Marchioness of Ailsa at Culzean Castle.

It was a wise move on the part of the local Entertainment Committee to have a transport section, which was presided over with great skill and energy by Dr. J. G. McCutcheon. In his work Dr. McCutcheon was ably assisted by, amongst others, representatives from the Caledonian Railway, the North British Railway, and the Glasgow and South-Western Railway.

MEDICAL MISSIONS RECEPTION.

Sir Donald MacAlister presided at a meeting in the Raudolph Hall on Friday afternoon, July 28th, after a reception given by Mr. and Mrs. A. Ernest Maylard to those attending the British Medical Association Annual Meeting. In a few striking sentences the Principal of the University commended the cause of medical missions. The original mandate to the first missionaries was "to preach the Kingdom of God and to heal the sick." This was recorded by a physician, and it was not for us to discuss our orders but obey them. Calling for an advance, Sir Donald MacAlister

said that the Church that ceased to grow at the margin had begun to wither at the heart. The religion that did not strive to gain the whole world was doomed to lose its own soul. Like a forest fire, it must go on or go out. Propagation was the law of its being, not merely of its well-being. Dr. J. Howard Cook, who had organized the meeting, explained that it was intended not to represent any one missionary society but the whole cause of medical missions. Dr. Albert Cook, who had been the founder of the great mission hospital of the Church Missionary Society in Uganda in the year 1896, gave a graphic description of the hospital with which he and his brother who had just spoken had been long associated. The hospital as it is to-day occupies a series of buildings on a beautiful hillside; it embraces every branch of medical and surgical practice. There are the usual blocks containing wards for men, women, and children, with good facilities for operations, about 1,020 having been performed during the year. The Wellecome dispensary and the Roosevelt block were referred to, the former the gift of Mr. Wellecome, and the latter opened by Mr. Roosevelt on his visit to Uganda. Special blocks have been erected for English patients and for Indians, and a motor block secures the lighting of the hospital and contains a good x-ray outfit. A medical school and maternity training school form part of a scheme for supplying the whole country with needed help. Dr. and Mrs. Albert Cook had recently engaged in an educational tour on venereal disease at the request of the Government, and they believed that from 40 to 90 per cent. of the population were infected. Dr. Dnnan Main, also of the C.M.S., spoke in the place of Dr. Christie of Manchuria, who should have represented Scottish missions. Both of them are graduates of Edinburgh University, and have built up great hospitals with medical schools in their respective centres. Dr. Main has recently received a gift of £10,000 from a generous Scottish donor for his medical school, and his great endeavour is to supply the medical needs of China through her own sons and daughters. Dr. Fletcher Moorshead, as medical secretary of the Baptist Missionary Society, suggested that the medical profession at home could best help the work (1) by influencing public opinion at home; (2) by helping to secure much-needed medical recruits; (3) by sending current literature such as the *BRITISH MEDICAL JOURNAL* to medical missionaries; (4) by helping to supply apparatus and equipment. Either he or Dr. Cook would be glad to put anyone in touch with doctors who needed help if members of the profession would communicate with them.

THE TEMPERANCE BREAKFAST.

A large number of members attending the Annual Meeting were entertained by Lord Rowallan (better known as Mr. Cameron Corbett, M.P.) at the National Temperance League breakfast in the University Union on July 27th. Among those present were Mr. C. P. Childe (President-elect of the Association) and Dr. Wallace Henry (Chairman of Representative Meetings). Allusion was made by the host to the removal from their midst during the year of Sir Alfred Pearce Gould, whose address last year at Newcastle would be long remembered. The address on this occasion was given by the Rev. Courtenay Weeks, M.R.C.S., who anticipated the discussion in the Medico-Sociological Section the following day by speaking of the vast amount of damage to the human economy which alcohol brought about, and urging that there was no place for the old traditional routine use of alcohol, although a considerable number of members of the medical profession were still in a backwater in this respect. It was the supposed food value of alcohol which proved so alluring to many, but he thought it was now generally agreed that the substance was deleterious to the higher centres and impaired the mental functions. He referred in particular to the report of McDougall and Smith to the Medical Research Council on the effects of alcohol during normal and fatigued conditions. Mr. Weeks concluded his address by remarking that he had no doubt himself as to the energy-giving value of alcohol:

during his work in the slams of London he had seen too many women with black eyes ever to doubt it! As the hour for the beginning of the work of the Sections was approaching, the breakfast-table discussion had to be curtailed, and a vote of thanks was accorded to Lord Rowallan for his hospitality, on the motion of Dr. Wallace Henry, seconded by Mr. C. P. Childe, and supported by Mr. McAdam Eccles. Mr. Childe referred to the great progress in temperance reform which had taken place of recent years. When he first went to Portsmouth there was ten times as much drunkenness as there was now. It was also formerly the custom to find the sherry always set out on visiting the patient's house; now one only found it at the funeral! Lord Rowallan, acknowledging the vote of thanks, remarked how greatly he had enjoyed the experience of being a patient at Guy's Hospital after a recent car accident, so that he came out feeling better than he had ever done in his life.

THE MINISTRY OF HEALTH.

THE annual report of the Chief Medical Officer of the Ministry of Health for 1921 has just been published. We gave last week a preliminary notice of the annual report of the Ministry, but Sir George Newman deals more specifically with strictly medical matters; his report will afford to the medical profession, to the public health service, and to the general public much food for thought. Happily it is published by the Stationery Office at the price of 1s. 6d. (it can be ordered through any bookseller), so that both its price and mode of distribution place it within the reach of all interested persons. It consists of an introduction, ten chapters, and some appendices, but in the crowded state of our columns at present we cannot do more than give a brief indication of its general scope. Sir George Newman has written his introduction with full recognition of the limitations which the present financial position of the country imposes. Speaking generally, he says that in the present state of national finance it is clear that the expenditure on public health matters "cannot be allowed to increase indefinitely, and that the strictest economy must be practised. The immediate business, as it seems to me, of every local authority is not to take one step more in expenditure until and unless they are fully satisfied that the work they have already undertaken is thoroughly economical and is rendering full interest. The public expenditure in dealing with tuberculosis, venereal diseases, and maternity and child welfare has inevitably grown to serious proportions, and, though relatively small (only 1 per cent. of local rates) as compared with that of other services, it is absolutely essential that no money should be laid out which is not immediately necessary in the interest of public health. Every pound expended must be made to yield the full value of a pound. Such a standard is not only necessary but it is eminently desirable in the interest of the work itself." He reminds local authorities that thrift and wise expenditure are parts of true economy. "If there be a certain sum of money to spend on communal health, it is inexpedient to indulge in stunts or spasmodic efforts in this direction or that, which arrest attention at the moment, rather than on a carefully considered policy, the principal elements of which must be regarded in an ordered sequence." Here and there we find some characteristic thrusts *ad hominem*, as, for instance, that the question, "What is the use of all our expenditure on health?" is often asked by persons "who do not reflect that their welcome presence among us, alive, alert, and competent, is itself the answer." The first chapter deals generally with the state of public health in England, the next with maternity and child welfare, and others with general epidemiology, with infectious diseases introduced from abroad, with tuberculosis, with venereal diseases, with the relation of food to health, with the insurance medical service, and with medical and sanitary administration. The last chapter reviews briefly the work of the Ministry in relation to medical intelligence, investigation, and international health. We hope to deal more fully with the report in an early issue.

THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual report of Sir Arthur Keith, F.R.S., Conservator of the Museum of the Royal College of Surgeons of England, gives particulars of numerous additions made during the year and refers to the large amount of research work carried out, much of it in the Pathological Department, which is directed by Professor S. G. Shattock, F.R.S. The Conservator is able to report the completion of the arrangements with the War Office with regard to the army medical war collection. Under the agreement come to last November with the Secretary of State for War, the Council of the College becomes responsible for the housing, display, completion, upkeep, and cataloguing of the collection, which will form an intrinsic part of the College Museum and be made available for inspection and study at the same times as other parts of the Museum. Specimens, however, will be at the disposal of the professors at the Royal Army Medical College for teaching purposes. By structural alterations in certain buildings attached to the eastern part of the Museum it will be possible to provide a large room to accommodate the war collection, which when complete will comprise 2,000 wet specimens and 500 dry specimens, besides drawings, radiograms, photographs, models, and casts. The actual preparation and description of specimens has fallen on Professor Shattock, with the assistance of Mr. Cecil Beadles, to whose services a high tribute is paid. When complete the collection will include the more representative specimens illustrating the severer forms of facial injury and the methods of plastic surgery selected by Major H. D. Gillies from the specimens preserved at Sidcup. Progress has also been made with the preparation of the Onodi collection recently presented to the College; the work is being carried on under the supervision of Mr. T. B. Layton, F.R.C.S., who has undertaken to investigate, describe, and catalogue the specimens. Professor Shattock reports that the large collection illustrating special pathology, which had been removed to the basement for safety during the war, has now been restored to the Museum and rearranged in a slightly modified way. Specimens recently added will be placed on view in one of the rooms of the Museum from October 9th to November 10th.

THE pressure of matter from the Annual Meeting of the Association compels us again this week to suspend the publication of the EPITOME.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

National Health Insurance Bill.—The Lords' amendments to the National Health Insurance Bill were considered in the House of Commons on July 26th and agreed to. These changes were of a small and technical kind.

Milk and Dairies (Amendment) Bill.—This measure, after being considered in Grand Committee, was taken on report in the Commons on July 28th, and was given third reading on August 1st. Very few changes were made from the text as originally presented, and as outlined in the BRITISH MEDICAL JOURNAL last week. On report on Clause 8, giving the Minister of Health power to make regulations to prevent danger to health from the importation of milk, words were added, at the instance of Sir Alfred Mond, to include in such power the right to make a regulation to prescribe the minimum percentages of milk fat and milk solids in dried or condensed milks.

Criminal Law Amendment Bill.—On report on the Criminal Law Amendment Bill on July 25th in the House of Commons, Clause 11, laying down that reasonable belief that a girl is 16 years of age shall be no defence, was subjected to the following qualification: "Provided that in the case of a man 23 years of age or under, the presence of reasonable cause to believe that the girl was over 16 years of age shall be a valid defence on the first occasion on which he is charged with an offence under this section." This addition was adopted by 99 votes to 65. The understanding was that it represented an arrangement between some members who supported the bill and some who were critical of it. On the second reading in the Lords, on July 27th, the Bishop of London, on behalf of those who introduced a similar bill last year, accepted the change. The bill had third reading in the Lords on July 31st.

The Sale of Arsenic.—Dr. McDonald asked, on July 26th, if, in view of the fact that large quantities of arsenic could be obtained from chemists by individuals merely signing a poison book, the

Minister of Health would take steps to discontinue this practice. Sir A. Mond replied that the sale of arsenic was governed by Sections 1 and 2 of the Arsenic Act, 1851, and by Section 17 of the Pharmacy Act, 1868. It would require further legislation, which would be considered, to deal with the point raised.

Voluntary Boarders in Mental Institutions.—Sir A. Mond informed Mr. R. Richardson, on July 26th, that during the year 1921 315 voluntary boarders entered licensed houses and 330 entered registered hospitals. During that year 194 voluntary boarders left licensed houses and 227 left registered hospitals of their own accord. Unless a patient was suffering from mental disorder of so acute a character that he was unable to appreciate what was taking place it was practically impossible for him to be certified without his knowledge, as had been suggested by the hon. member.

Mental Service Cases.—Captain Loseby asked, on July 19th, whether the Minister of Pensions was aware that many ex-soldiers of good social position, and in no sense dangerous, who owed their state entirely to service during the war, were still confined in pauper lunatic asylums? Mr. Macpherson replied that both ex-service and civilian patients in mental asylums and elsewhere differed in social status. Some of them, though neither dangerous to others nor actually suicidal, were quite unable, on account of their unfortunate mental condition, to look after themselves, and could not otherwise be suitably cared for. Service patients were on the legal footing of private patients, and might therefore be removed at the instance of their responsible relatives unless the medical superintendent certified that they were dangerous to themselves or others. In reply to a further question, Major Tryon stated, on July 20th, that the lowest rate paid for the maintenance of an officer whose admission to an asylum had been arranged by the Ministry was 2 guineas a week. There were in addition seven officers in country and borough asylums at rates ranging from 28s. 10d. to 37s. a week. None of these cases had been placed in the asylum by arrangement with the Ministry, but were allowed to remain there for various reasons. Maintenance of a service patient in asylums as about 36s. a week. Mr. Macpherson stated number of ex-service men of all classes under treatment in asylums, in respect of whom allowances are paid or credited was 6,800.

Ex-Service Men under Care.—In reply to Captain Loseby, on July 25th, Major Tryon said that when the condition of a patient in one of the Ministry Neurological Hospitals deteriorated towards insanity he was kept apart from the other patients, and every approved means of cure known to modern science was tried. Should the treatment fail to arrest the development of the malady and certification became necessary, steps were at once taken for the patient's removal to a mental institution approved by the Board of Control.

Soldier Homes and Hospitals in Malta.—Sir J. Randles asked, on July 26th, what steps had been taken to give security to those responsible for soldiers' homes, hospitals, seamen's rests, and such buildings as had been erected on lands held from the War Department in Malta, but which, under recent arbitration, were liable to be disturbed by the civil authorities. Mr. Churchill said the responsible government at Malta might be trusted to deal with the authorities in charge of these institutions in an equitable spirit. He would forward the question and answer to the Governor of Malta.

Prevention of Conception.—Mr. Hailwood asked, on August 1st, whether the Government intended to introduce legislation on the lines of the French law of 1920 making it a punishable offence to publish or distribute books or pamphlets advocating or teaching the prevention of conception, or offering for sale or advertising the sale of articles designed for the like purpose. The Home Secretary said that it was the duty of the police to take proceedings in any case where books of an obscene character were being circulated, but it could not be assumed that a court would hold a book to be obscene merely because it dealt with the subject referred to. There was no present intention of introducing legislation.

Brief Notes.

Major Tryon has stated that the speech specialists employed at the Kensington, brought about a temporary, but steps had been taken to deal with the was no reason to doubt that they would prove satisfactory.

In reply to Dr. McDonald, on July 26th, the Minister of Health said that he was satisfied from inquiries made that cocaine was essential to the medical profession, particularly in ophthalmic surgery and laryngology. Although dental surgeons were not unanimous, many regarded cocaine as essential for certain operations.

Sir A. Mond stated, in answer to Mr. Mills on July 27th, that Sir Wilmot Herringham was appointed a member of the General Nursing Council on the nomination of the Board of Education.

The Secretary of State for War has stated that the department for compiling statistics of disease in the army during the war has to deal with thirty million hospital cards; delay was therefore inevitable, and this explained why statistics as to small-pox cases and deaths had not yet been issued.

A man's eligibility for pension is not affected by his removal from duty on one or more occasions, except in so far as it may afford evidence of the existence of the disability, and thus help to establish connexion between the disability and military service.

The Home Secretary has stated that the practicability of employing distinctive colours for poisons such as arsenic and strychnine is under consideration.

England and Wales.

WELSH NATIONAL SCHOOL OF MEDICINE.

The Committee of Management of the Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England has made a report on the application from the Welsh National School of Medicine to be recognized for the complete curriculum. The Committee discussed various points arising out of the application with a deputation from the University of Wales, consisting of Lord Kenyon, Pro-Chancellor, Chairman of the Board of Medicine, Principal A. H. Trow, Sir William J. Thomas, Bt., Sir William H. Diamond, Mr. D. W. Evans, Professor A. M. Kennedy, Professor Eweu J. Maclean, and Professor A. W. Sheen. The Committee was generally satisfied with the provision made for teaching, and the Royal Colleges have resolved:

That the Welsh National School of Medicine be recognized provisionally for the complete curriculum from October 1st, 1922, for one year, and that provided the following conditions are fulfilled not later than October 1st, 1923, such recognition become permanent, namely:

1. The total number of beds, exclusive of cots, available for the teaching of medicine in King Edward VII Hospital, Cardiff, shall not be less than 80.
2. Of these 80 beds, not less than 30 shall be allotted to the professor of the medical unit.
3. All physicians, surgeons, assistant physicians, assistant surgeons, and physicians and surgeons in charge of special departments at King Edward VII Hospital shall be recognized as teachers of the University of Wales.
4. Clinical clerkships and dresserships shall be provided for all students in professional and non-professional units.
5. Courses of instruction in all special departments required by the Regulations of the Examining Board in England shall be provided.

CARDIGAN MEMORIAL HOSPITAL.

The people of Cardigan and adjacent districts resolved that the local memorial to men who had fallen in the war should take the form of a hospital in Cardigan, to serve the neighbouring districts of Cardiganshire, Pembrokeshire, and Carmarthenshire, for the town stands near the point where these three counties meet. A considerable sum of money was collected and the committee was able to command the enthusiastic help of Sir John Lynn-Thomas, who, since his retirement from the active staff of King Edward VII Hospital in Cardiff, has gone to a short distance from Cardigan. At his Priory, a private house standing in its own grounds just outside Cardigan, was purchased, and under his supervision and with generous help from him has been fitted up as a hospital, possessing all the facilities and appliances necessary for surgical as well as medical work. He has become consulting surgeon to the hospital, as has also Mr. J. O. D. Wade of Cardiff, while Dr. Arbour Stephens of Cardiff has become consulting physician. The staff of the hospital consists of practitioners resident in the neighbourhood.

The hospital was formally opened on July 28th by Dame Margaret Lloyd George, D.B.E. She was received at the Cardigan Public Buildings, and a procession was formed to the hospital. Mrs. Lloyd George having opened the main door of the hospital with a silver key presented to her by Lady Welby-Parry-Pryse, president of the hospital committee, a meeting was held under the presidency of Alderman John Evans, chairman of the Memorial Committee. Mrs. Lloyd George congratulated Cardigan and the district on having chosen so practical a form of war memorial; such hospitals, she said, were greatly needed in Wales, and she was glad to know that they were being established in other districts also. Sir Robert Jones of Liverpool, who followed, spoke on the importance of preventive surgery, and said that there need hardly be a cripple in the country if all did their duty. Very rarely indeed should a pair of crutches be seen, and there was no cripple whose condition could not be ameliorated if he could have the advantage of sound surgical treatment. Sir Charles Ruthen, Director-General of Housing, expressed the view that much disease was due to bad housing conditions, and that if people could have better houses hospitals would become unnecessary. Sir John Lynn-Thomas, who spoke next, traversed this opinion; while admitting that tuberculosis might be enormously diminished if houses were better, there were, he said, other serious diseases due to quite different causes;

he instanced appendicitis, which was to be attributed to imperfect teeth. Dr. Arbour Stephens, who also spoke, dwelt on the means which could prove effective for the prevention of heart disease. A vote of thanks to Mrs. Lloyd George was proposed by the Lord Lieutenant of the County and duly acknowledged. The Chairman announced that Sir John Lynn-Thomas had presented the institution with radium which in pre-war days was of the value of £200. A cordial vote of thanks was passed to him for this gift and for the large share he had taken in the establishment of the hospital. The hospital has been started on a modest scale, but the number of beds can easily be increased, and already, we understand, many applications for admission have been received and a number of serious operations successfully performed.

MILK PROSECUTIONS.

Medical officers of health and others concerned with public health administration will read with some astonishment circular No. 325 issued by the Minister of Health on July 17th to authorities concerned in the Sale of Food and Drugs Acts.

The circular commences by stating that the attention of the Minister has been called to a case in which a milk vendor was prosecuted for selling milk deficient in fat; the vendor had previously held a good record, and on it being proved that special circumstances existed to account for the fat deficiency on this occasion the local authority withdrew the prosecution. The circular goes on to state that the Minister

"is advised that conditions of a purely temporary character may on occasion cause the milk from cows, which normally give milk of the proper fat content, to be below the limit laid down in the Sale of Milk Regulations, and that the results of an isolated test cannot be regarded as conclusive evidence that the milk in question is in general below this limit. The Minister is therefore of opinion that it is extremely undesirable that a prosecution should be based upon the results of an isolated test when other tests of the particular milk supply have proved satisfactory." It is suggested to local authorities that in the cases of "those vendors who are doing their best to secure that the milk they sell is of good quality," as judged by previous tests, prosecutions should be instituted only where a series of tests have shown repeated default.

This circular, provided attention is paid to it by efficient local authorities, which is, perhaps, doubtful, would virtually effect on this subject a change in the law by means of administrative action. The milk purveyor would have to be proved to the satisfaction of the local authority to be a systematic adulterator before proceedings could be taken against him. The circular does not state in what way it would be possible to make the evidence admissible so as to be able to prove in court the results of the repeated preliminary tests, taken formally or informally. Samples of milk are usually taken from purveyors at irregular and often at infrequent intervals, sometimes not more than once a year or even longer. Sometimes a considerable interval is allowed to elapse even after an adulterated or suspicious sample is discovered, before again testing the vendor's milk. Under the suggested procedure the purveyor would be protected if a first sample was reported to be not genuine and this protection would continue even if a second and possibly a third sample were taken within a reasonable time after the first sample and had yielded similarly unsatisfactory results. The existing law is that if anyone sells an article of food to the prejudice of the purchaser which is not of the nature, substance, and quality of the article demanded, he has committed an offence for which he is liable to be prosecuted. Members of local authorities and their officers as a rule act reasonably, and although there is no legal obligation on them, prior to taking out a summons, to ascertain why the milk sample is below the presumptive standard, nor to require an explanation from the vendor as is provided under the Milk and Cream Regulations (dealing mainly with the addition of preservatives), in practice before a prosecution is ordered consideration is given to such a point as the amount of adulteration, and to any circumstances bearing on the matter which may be known. It is a fairly common practice to take an "appeal to the cow," that is to say, a specimen is taken by the sampling officer at the farm with due precaution so that what he secures is a specimen of the milk which ordinarily should be dispatched from the farm. It is not customary to order prosecution for low amounts of adulteration; a caution is usually given. This often arises where "toning" is practised, and sometimes the vendor "overtones"—that is, he lets down the strength of his milk below the limits of 3 per cent. fat and 8.5 per cent. solids not fat laid down in the

Salvo of Milk Regulations. Below these limits the milk is deemed not to be genuine unless the contrary is proved.

In general it might be thought that some local authorities do not prosecute sufficiently often in milk cases, which is quite contrary to the suggestion of the circular. In the present state of the law on the subject, however, local authorities can hardly be blamed if often they refrain from instituting legal proceedings. According to the appeal cases decided in the High Court, any fluid proved to have been derived from the udder of the cow which appears to be milk is, legally speaking, milk, no matter how the cowkeeper has mismanaged his herd or what is the chemical composition of the fluid purporting to be milk.

The question of variations in the amount of fat in genuine milk is one which does not here arise; it depends upon a number of factors, but it is held that the mixed milk of a herd properly managed practically never falls below the low limits laid down in the Sale of Milk Regulations, 1901 (which, after taking into account the above considerations were issued by the Board of Agriculture and Fisheries, a body which has little concern with the interests of the consumer, but in this matter has always been regarded as acting as the friend of the farmer), but if such milk did fall below these limits a satisfactory explanation could be furnished which would rebut the presumption that the milk had been adulterated; in other words, the producer already has ample legal protection according to the cases decided in the High Court.

Among the causes of fat deficiency in milk, most of which are within the control of the cowkeeper or milk vendor, may be mentioned "toning," irregular intervals between milkings, defective or improper feeding, breeding of cows for quantity of milk and not for quality, keeping the "strippings" (the after-milk, which is the richest) for the calves, and illness of the cows. Even if existence of any of these conditions can be proved (except "toning") the cow is held to be producing what legally is considered to be milk, whatever its composition. The defendant merely has to prove that the milk is sold as it came from the cow. (*Hunt v. Richardson* (1916) 2 K.B. 446, 85 L.J.K.B. 1036; *Grigg v. Smith* (1918) 82 J.P.R. 2; *Williams v. Rees* (1918) L.G.R. 159; *Scott v. Knowles* (1918) 55 Sc.L.R. 167.)

A further protection to a milk seller who is not the producer of this milk is that he can buy it under a warranty, and having proved this there is a sufficient answer to the charge so far as he is concerned.

Taking all this into account, it might be considered that instead of endeavouring to place further obstacles in the way of successful prosecutions, Sir Alfred Mond might have introduced legislation to cover the points referred to above; a suggestion to this effect was in fact thrown out by Lord Reading, when Lord Chief Justice, in his judgement in *Grigg v. Smith*, in order to prevent milk from being sold with an undoubted deficiency of milk fat as compared with the usual amount owing to the farmer, the successful appellant in this case, having, it was admitted, kept the "strippings" for the calves.

It must be assumed that all these facts were at the disposal of the Minister of Health, and he must be aware of the great difficulties experienced by the public in obtaining a reliable milk which reaches a reasonable chemical standard. Measures taken to secure a clean and tubercle-free milk have nothing to do with the present issue which, though involving a chemical point, is none the less of considerable importance.

A statement has appeared in the press to the effect that protests against the circular in the daily papers have been made under a misapprehension. This explanation though unofficial is represented to have been derived from official sources, and is to the effect that the circular very clearly and definitely refers to a particular type of case—namely, that in which regular inspection has been made which revealed that normally the milk from that place was satisfactory. The explanation proceeds further to refer to premises which are under official supervision, apparently the small number of those from which Grade A and Grade A certified milk is produced.

A careful reading of the circular leaves the impression either that this statement is designed to explain away and withdraw from the retrograde policy advocated in the circular, or that the circular was drafted in such obscure terms that its real import was obvious only to those who issued it.

No doubt questions will be put to the Minister of Health in House of Commons as to the source of the advice upon which he authorized the issue of circular No. 325.

POST-GRADUATE COURSES IN LONDON.

As has been already announced, a two weeks' post-graduate course in general medicine will be held under the auspices of the Fellowship of Medicine and Post-Graduate Medical Association from Monday, September 11th to Friday, September 22nd; the following hospitals will participate: Hospital for Consumption, Brompton, Hospital for Epilepsy and Paralysis, Bathlow Royal Hospital, National Hospital for Diseases of the Heart, Middlesex Hospital, St. George's Hospital, the Children's Clinic Western General Dispensary, and the Royal Eye Hospital. A syllabus giving full particulars can be obtained from the Secretary to the Fellowship at 1, Wimpole Street, W.1. A short course on common tropical diseases will be held at the School of Tropical Medicine, Eudleigh Gardens, in October next. It will consist of systematic lectures illustrated by clinical demonstrations on the pathology, symptoms, diagnosis, and treatment of the several diseases and their sequelae. Copies of a preliminary syllabus can be obtained from the Secretary to the Fellowship of Medicine, and the detailed programme will be issued later.

CENTRAL MIDWIVES BOARD.

The Central Midwives Board met on July 27th, Sir Francis Champuoy presiding, when a letter was received from the Manchester and Salford and District Branch of the National Council of Women forwarding the following resolution which had been passed by the Council:

This Branch of the National Council of Women is convinced that the present training of midwives is entirely inadequate to fit them for the heavy responsibilities of their work, and urges upon the Central Midwives Board and the Ministry of Health the necessity for longer and more comprehensive training. It urges further that before making any such change careful investigations shall be made, to this and other countries, and the views of midwives and others in all branches of maternity and infant welfare work shall be considered.

The Board decided to take the resolution into consideration when the rules as to training are revised, and expressed the desire that any information at the disposal of the District Branch of the National Council of Women might be forwarded.

The following were approved as lecturers: A. C. Palmer, M.B., F.R.C.S., H. F. Parker, M.D., A. H. Richardson, M.B., F.R.C.S., and Miss Mabel G. Brodie, M.D.; Miss Lily A. Baker, M.B., was approved as a teacher. The Board recorded a vote of deep sympathy with the family of the late Sir Edward Malins, and its appreciation of the valuable services rendered by him as an examiner at the Birmingham centre.

Scotland.

SIR JAMES HODSDON.

SIR JAMES HODSDON, K.B.E., M.Ch., F.R.C.S. Edin., has, on the occasion of his retirement from the surgical staff of the Royal Infirmary, Edinburgh (he was senior surgeon) received a presentation from his old residents. It took the form of a silver plate reproducing some of the vessels found at Traprain Law. Sir James Hodsdon was President of the Royal College of Surgeons of Edinburgh from 1914 to 1917, and represents that college on the General Medical Council.

LAWS OF LIVINGSTONIA.

On the morning of Friday, July 28th, more than a hundred friends sat down at breakfast in Edinburgh with Dr. Robert Laws, who is returning to his work as a medical missionary in Central Africa. It is forty-seven years since Dr. Laws went out to Lake Nyasa to establish there a mission in memory of Dr. Livingston, and the history of that work so successfully accomplished and of the man who has been mainly instrumental in accomplishing it have been published within the past few months in the book entitled *Laws of Livingstonia*. During his visits home at rather long intervals Dr. Laws has always endeavoured to bring himself abreast with all recent work in medicine, and during the past winter he was to be seen climbing the stairs with the other students to the pathology department in the University of Edinburgh to the study of tropical diseases. At the age of 71 there is something almost heroic in facing student life and in going back to work in Central Africa; but Dr. Laws has accomplished so many great things in his adventurous, pioneering, and devoted life that possibly he may not think so.

At any rate he gave no hint of weariness or weakness at the breakfast, where he was surrounded by many old and new friends. Whilst the majority of the guests were members of the various churches and of missionary societies, the medical profession was represented by Sir James O. Affleck, Dr. J. W. Ballantyne, and Dr. Robert Thin. Dr. Laws, in addition to holding the degree of M.D., is D.D. and F.R.G.S.

New South Wales.

SYDNEY UNIVERSITY COMMEMORATION.

It was decided by the Senate of the University of Sydney and the Professorial Board that the proceedings in connexion with the annual commemoration should this year be spread over two days. In the Great Hall at 11 a.m. on May 18th there was the annual commemoration of benefactors of the University, and degrees were conferred. In the afternoon there was held on the Sports' Oval the 'Varsity' championship sports in the presence of the Governor-General and his Staff. In the evening there was a conversation in the Great Hall, the guests being received by the Chancellor, Sir William Cullen, and Lady Cullen. On May 19th the students had a procession of humorous "side shows" through the city to the State Governor, Sir Walter Davidson. Association Students' song in the Quadrangle and a mock trial under the auspices of the Law School were held in the afternoon. At 4.30 lectures were given by Professor Griffith Taylor on native dreams, and Professor Fawcett on the modern theory of races in Australia, by Dr. Lovell on the theory of the Engineering School, and a concert. There has been a great fall in the number of new entries at the Medical School, only about 86 new students this year, as compared with over 240 a year ago. The fall is attributed partly to the increase in the fees, partly to the lengthening of the course, and partly to a general recognition that the profession is already overcrowded.

TROPICAL AUSTRALIA.

Some interesting evidence was recently given before the Commonwealth Public Works Commission which is at present considering the question of the north-south railway. Professor Priestley, the professor of chemical physiology in the University of Sydney, stated that he had lived in the tropics of Australia for some years, while he was at work in the Institute of Tropical Diseases in Townsville, and that so far there is nothing to show any deterioration of health through living in the tropical climate of Australia. Investigations, particularly with children of from seven to fourteen years of age, yielded no evidence of any sort of physical deterioration: the subjects examined compared favourably with those of any other part of Australia. Although there was a noticeable pallor in the skin, examination of the blood did not reveal a special anaemic condition. There was, however, no real coarsening in the tropics. Women living in the tropics have to work under very unfavourable conditions, housing is bad, kitchens are frequently built entirely of galvanized iron, and domestic help is extremely hard to get and very expensive. Nearly all the tropical diseases found in other countries were absent, though at isolated places there was a little malaria. Professor Priestley further stated that he had examined up to the third generation of children born in the tropics and had found no signs of deterioration in them; during the war he had examined recruits from Central Australia and found them to be a fine body of men.

BUBONIC PLAGUE.

At a recent meeting of the members of the Sydney Division of the Public Health Association of Australia Dr. W. G. Armstrong, the Director-General of Public Health, stated that the worst danger of the plague, so far as New South Wales is concerned, is passed for the season, but there is serious danger of a virulent recrudescence during the next summer months unless all possible preventive measures are taken in the interval. He said that it had been definitely determined that the plague was spread mainly by two kinds of fleas, the rat flea of cold countries and the rat flea of warm countries.

Correspondence.

THE CAUSE OF INFLUENZA.

SIR,—I was particularly interested in your *précis* of Professor McIntosh's report on influenza to the Medical Research Council which you publish in the JOURNAL for July 22nd, 1922 (p. 137), because I had come to the same conclusions as his three years ago (BRITISH MEDICAL JOURNAL, March 1st, 1919). There is one piece of evidence not available in a laboratory which he leaves out, and that is the prevention and rapid cure (abortion) of the disease with a pure antigen of the bacillus. You say in criticism that the influenza bacillus appears in human beings apart from influenza. This is not my experience. I have never known a case harbouring the influenza bacillus that had not had an attack of influenza, and was therefore a carrier, or had been in contact with a case. In my laboratory the medium used for ten years—namely, unheated human blood agar, for growing all microbes for antigen purposes will always grow the influenza bacillus provided it is alive in the material, and, therefore, it is very striking that we never saw the influenza bacillus until the pandemic in 1918, and since then it appears with the epidemics and disappears with them.

As to the special filter-passing microbe, I hope we are getting away from the idea that filter passing is, solely the property of a special class of ultra-microscopic microbes that never can become large enough to be seen. Probably very many microbes, if grown under suitable conditions, can become small enough to pass through filters. This has indeed been proved. Moreover, filters vary in the size of their pores, and some of them have cracks. Finally, we must seek postulates other than Koch's for the identification of the infectivity of at least 90 per cent. of human infections since the crucial experiment—namely, the infection of other human beings with the isolated organism—is not open to us.

I have suggested as a beginning that:

1. If the microbe is an epidemic one and the disease is prevented and aborted with a pure antigen of the microbe, that microbe is the cause of the epidemic. These criteria have been satisfied by the influenza bacillus and by a new microbe I have recently isolated—namely, that of fowl diptheria very similar to it. And also, of course, by the *B. typhosus* and *paratyphosus*.

2. If the microbe is causing a definite lesion in the body, such as Bright's disease or encephalitis lethargica (BRITISH MEDICAL JOURNAL, March, 1920, and April, 1921), and a pure antigen produces a focal reaction at the site of infection, then that microbe is the cause of the disease if the infection is a pure one or one of the causes if the infection is a mixed one. —I am, etc.,

W. M. CROFTON,

Laboratory of Special Pathology,
University College, Dublin.

July 25th.

VOLUNTARY v. STATE HOSPITALS.

SIR,—The attitude adopted by the British Medical Association at their Glasgow Meeting in regard to the question of voluntary hospitals is one that should commend itself to every member and non-member of the Association; it is a question that seriously concerns not only them but the entire population of the United Kingdom. Those who can appreciate the great privileges connected with voluntary hospitals as opposed to State hospitals, and the overwhelming advantages of an independent medical profession, would bitterly lament the introduction of State hospitals and a State medical service. Once the State has to budget regularly for the support of the hospitals of the country, even if its allotments are not very material, it can legitimately claim to have something to do with their administration and organization. This is the initial stage—the insertion of the thin edge of the wedge; the next step will be the conversion of those institutions into State or national hospitals, and their medical and surgical staffs will become part of a State medical service. In my opinion this conversion of hospitals and the creation of a State medical service would be one of the most fatal blows that could be given to the progress of hospital administration and work and to the independence of opinion of the most talented medical men in the kingdom. I believe it is only medical men, who have been bound by the four corners of a series of "red books" for the greater part of a lifetime, who know how to value reasonable freedom of action and

The progress of the epidemic in India, and on previous occasions in New South Wales, had shown that there was a marked tendency for these fleas to die off during the cold weather, and they could therefore assume, with reasonable probability, that Sydney had at present passed the most critical period of the disease. The team work of the Block Associations had been one of the most remarkable examples of the help the people as a whole could give to the public health officials that he had ever experienced. Precautionary measures, however, must not be relaxed for a day during the coming months; not only in the way of eradication of rats, but by united efforts to render the offices and warehouses of the city rat-proof. Dr. Harvey Sutton, the City Health Officer, said one good result of the present preventive campaign was that it sought the co-operation of all sections of the community, from the architect who designed rat-proof houses to the housewife who kept her place clean and so deprived the rats of food. Dr. R. Dick, Senior Medical Officer to the Board of Health, urged the importance of making every effort to prevent the spread of the plague-infected rats to the country towns, where food was plentiful and the destruction of rats very difficult owing to the rank growth of vegetation. The danger of plague throughout the country had increased very much in recent years owing to the fact that New South Wales had become a large wheat-growing State, and so that there was always plenty of food for rats and mice. Professor J. D. Stewart, Professor of Veterinary Surgery in the University of Sydney, said that so many diseases affecting human beings were carried by rats and mice or their parasites that man for his own protection, quite apart from the damage done to property, should wage incessant warfare against these animals.

"CLEAN THE CITY CAMPAIGN."

A "Clean the City Campaign" was recently organized by the United Block Association with a view to enlisting the full sympathy and efforts of the citizens in getting rid of rats, fleas, and dirt. In a series of practical suggestions issued by the United Block Association, emphasis is laid on the necessity of ridding the city of rats and fleas, and it is pointed out that this can be done only by killing the rats and by getting rid of all accumulations of dirt and garbage, either of the home or of the office. The work could be facilitated by the removal of food so as to starve the rats, and by closing up the eisterns so that the rats could not get water. All fowl runs should be cleaned out and all garden refuse destroyed.

At a meeting of women, convened by the National Council of Women at the request of the Citizens' Block Association, to discuss the prevention of the spread of the plague, a large number of institutions were represented. Dr. K. A. Bryce spoke of sanitary methods of dealing with garbage. Dr. Grace Boelke complained that there were not enough health officers, and suggested the appointment of women to carry out health work. She urged the importance of attention to the tourist resorts, so that food and rubbish were not left lying about. It was eventually decided to appoint a subcommittee to go into the questions of forming Block Associations in the city and suburbs, and of giving health lectures in the poor and crowded parts of the metropolis.

At a large and representative meeting of business men to consider the best means which should be adopted to organize a thorough clean-up of the city, the Lord Mayor, who was in the chair, thanked the business men of Sydney for the promptitude with which they had responded to his appeal. He stated that the city had been divided into twenty-eight blocks, and already twenty associations had been formed. Dr. Armstrong, Director-General of Public Health, said the Board of Health was grateful to the business men for their energetic co-operation in regard to rat destruction, but he wished to emphasize the fact that for many years to come the danger of a plague outbreak would persist, and that the organization of the city into blocks could not be merely a temporary measure of protection. In case of any rat-infested premises coming under the notice of the Block Association, if the owner refused to do anything to rid them of the rats, the Health Department or the City Council would take the necessary action to compel him to do so.

During the campaign week many meetings were held and lectures and addresses were delivered in the city and suburbs. In addition the active sympathy of the clergy was enlisted, and special attention was directed in many of the churches to the important matters of health.

liberty of personal opinion in professional matters. A State medical service, which must have some sort of definite policy, has to control within certain limits the published opinions of its officers. One of my functions as D.D.M.S., Army Headquarters in India, was to censor the papers which medical officers in military employ submitted for approval by the D.M.S. before they appeared in the medical press (articles for the lay press were, of course, subject to the rules laid down in the *King's Regulations*). It was seldom that we had to make any suggestions, but occasionally young and ambitious men, from lack of experience or other reason, went off the rails. One naturally admired initiative, personality, and independence, and fostered them when these did not clash with official considerations, and one felt it to be a serious matter to damp the ardour of a possible budding genius; in short, some sort of control is indispensable in a State service. Similarly, once State hospitals are introduced every article of their equipment must, for uniformity and convenience of supply, be scheduled, and practically everything required not on the list can only be procured after obtaining special sanction, which may take months or may be withheld. As a regimental medical officer I had to buy my own wash-basin for personal use, as only one was allowed for the whole hospital, and for fifteen years I had to purchase my own nail brushes because they were not included in the list of authorized articles.

State hospitals mean stagnation in progress in hospital work; a State medical service means suppression of initiative, personality, and independence; with both these factors the interests of the public are inseparably connected.

The public, and especially the classes for whose benefit voluntary hospitals exist, should, however, fully realize their personal responsibilities; if they are to continue the free use of these institutions and to have the very high standard of medical and surgical treatment obtained in them, they must provide the working expenses. Every person in the kingdom should pay something towards the upkeep of these hospitals. Those who cannot afford more should pay even a few shillings a year to their local hospital fund.

Every man should avail himself of every ing this duty to the people of the works. If the people do not meet the expenses connected with voluntary hospitals the change apprehended will, it is all but morally certain, become inevitable.—I am, etc.,

P. HENRI,
Major-General I.M.S.

Westward Ho, July 23th.

THE TEACHING OF PSYCHOTHERAPY.

SIR,—I wish to point out one or two possible fallacies in Dr. Macdonald Ladell's letter on this subject (p. 191). He rightly states that the remedy for lack of appreciation of psychotherapy lies in the education of the profession in its scope and usefulness, but goes on to say that this can only be done by teaching psychotherapy itself. Surely a more effective method is, as in the case of operative surgery, to let the practitioner see the patient before and after treatment. Dr. Ladell suggests that the specialty of psychotherapy should be looked at from the same angle as a surgical operation. But this is already done, and in the case of a fully qualified specialist the general practitioner is usually willing to let the case go out of his hands for a long time. Naturally, however, as the issue involved is in its way often no less serious than that involved in an operation, the medical attendant hesitates unless he has evidence that the specialist is as well qualified as the operating surgeon. In the case of the latter this is generally shown by the possession of a higher diploma and a hospital post at which good work is done. For a specialist in psychotherapy similar qualifications are not usually desirable. But he should produce evidence of similar long training; he must go through a full analysis at the hands of a competent analyst, or adopt some equally satisfactory course. In addition he should study some or all of the allied subjects—neurology, insanity, and mental defect—and much else besides. This involves time, expense, and hard work.

Dr. Ladell recognizes that analysis cannot be taught before a crowd of students, but his suggestion that some half-dozen keen spirits should work systematically at the interpretation of their own dreams under the guidance of a lecturer does not offer a solution. The situations, and therefore also the dreams, dealt with in analysis are extraordinarily delicate and individual, and cannot be discussed profitably with any-

one except the analyst. The six students working with their lecturer inevitably make the work machine-like and therefore valueless. They are not likely to shed any light on those problems of dreams which are still obscure. Certain typical dreams can be explained in a lecture, but no one can learn analysis from lectures, but only by living through the psychological experiences, emotions, and gradual enlightenment his patients must face later. Dr. Ladell seems to suggest that psychotherapy is now a science; analysis, however, never can become a science any more than the differences between the schools of Freud and Jung can be reconciled; some of these are fundamental, and not mere differences of technique.

In conclusion, I would agree with your article in the issue of July 15th that whenever possible specialists in psychotherapy should only accept patients through a general practitioner; if this is done they will not have to complain of the lack of recognition they get either from the public or their own profession.—I am, etc.,

Birmingham, July 29th.

W. A. POTTS.

SIR,—I have been interested in Dr. R. Macdonald Ladell's letter on the teaching of psychotherapy. At the Tavistock clinic for functional nerve cases we naturally encounter the difficulties to which he refers, and our attempt to meet them has been on the following lines. If the practitioner who desires instruction in psychotherapy lives near at hand, and is in practice, we get him to attend a three months' course of lectures and suggest a course of reading for him. If at the end of that time his enthusiasm shows no signs of waning, we suggest that he should be analysed, either by a member of the staff or by some other analyst. It then becomes the duty of the analyst to say when he may begin treating other cases. He then starts with one or two cases, of which a provisional diagnosis has already been made by a senior member of the staff. He is expected to devote not less than two hours weekly to each case, and he has a weekly interview with me or with one of my colleagues to talk over his cases and discuss his difficulties.

When the practitioner has only a limited period of, say, three months at his disposal, as in the case of colonials, I.M.S. men on furlough, etc., the procedure has necessarily to be compressed, and not infrequently we postpone the practical part of the training to a subsequent furlough.

The main difficulty is to side-track without offence the enthusiasm of those who, in their ignorance, believe that in the course of a week or two they can acquire the technique of hypnosis, and with this equipment return to work as psychotherapists.—I am, etc.,

London, July 31st.

H. CRICHTON MILLER.

THE PREVENTION OF SIMPLE GOITRE.

SIR,—The article on simple goitre by McCarrison in the *Journal* for July 8th raises

a question which medical men cannot honourably allow to remain unanswered.

We are given to understand that simple goitre is the easiest of all known diseases to prevent, and the method of prevention—the exhibition of iodine—one that could be applied almost anywhere.

There are, of course, as McCarrison says, a number of factors that combine to render the available iodine in the food relatively insufficient—for example, age, sex, puberty, pregnancy, menstruation, season, infections and climate, food, altitude, distance from the sea, food balance (excess of fats increasing the need of iodine), etc., and in any particular case these matters would have to be taken into account; we would, for instance, deal with a contaminated water supply or prevent constipation and oral sepsis.

If goitre, then, can be prevented let us as a profession, laying aside any rivalry, enthusiastically initiate and carry on a preventive campaign.

To those of us in the public health and school medical service certain measures of dealing with the problem will occur. In my report on the school medical work in Bath for 1919 I gave details regarding the prevalence of goitre among school children and certain factors relevant thereto, and in an article in *School Hygiene* (November, 1920) I considered the

question generally. Regarding prevalence, I give an extract from my paper in *School Hygiene*:

"During the years 1918-19 notes were taken of various matters relating to this disorder and its prevalence among 7,025 school children in Bath. The cases were distributed as follows:

Ages.	Boys.		Girls.	
	Numbers.	Goitres.	Numbers.	Goitres.
Over 14 years ...	63	1	46	2
12-14 " ...	1,044	11	1,173	25
10-12 " ...	226	2	191	6
8-10 " ...	910	1	912	11
6-8 " ...	355	0	335	5
Under 6 " ...	831	0	813	6

"There was thus 0.53 per cent. among the 3,548 boys, and 1.50 per cent. among the 3,477 girls. The percentage became higher in the pre-pubescent period after ten, no cases were found in boys under eight, and none recorded on the 190 cards received by me from infant clinics.

"An appendix on the subject by Dr. A. C. Turner in Dr. Warner's report for Leicester, 1919, showed 1.8 per cent. among 11,244 children, distributed as 0.2 per cent. in girl entrants, 0.3 per cent. in boy entrants, and in leavers 5.8 girls and 1.1 per cent. of boys. Dr. Turner thought the incidence greater in well-favoured residential districts, and although for Bath I thought so too, I am not now convinced of this.

"In one Bath school there appeared to be a special outbreak, with 15.7 per cent. among the girls, 4.3 per cent. among the boys, and 1.9 per cent. among the infants; of these cases 8 were below and 10 above ten years old, and the disease appeared to have come on fairly rapidly.

"As regards other districts, Dr. Hutt, in an article in the *Lancet* (April, 1911), gave an analysis of cases in Warrington, and quotes figures for Brighton as 0.8 per cent.; Exeter 0.3 boys and 2.4 girls, average 1.4 per cent.; Middleton 0.2 boys, 0.7 girls, average 0.45; Burton 0.6; Derbyshire 0.5 girls and 1.0 per cent. of five and thirteen; I gives 0.5 boys and 1.7 girls, average 1.1 per cent., among 4,603 children.

"On the other hand the *Medical Officer*, April 19th, 1919, quotes enlarged thyroid 56.0 per cent., and very definite enlargement 13.0 among school populations in the Great Lake Districts of North America. Dr. Sutton in Australia found 7.0 per cent. slight and 5.0 per cent. very definite enlargement among Geelong high school girls. McCarrison quotes districts of prevalence in India, whilst a medical friend of my own, Dr. Metcalfe Chambers, tells me that he has not seen a case among 28,000 Asiatic hospital patients in the Malay States. McCarrison only counts visible enlargement of the gland; palpable glands not visibly enlarged he does not include as goitrous."

Since writing the above I have found in Glossop (Derbyshire High Peak) that, taking boys and girls as a whole, the percentage among 1,222 was 2.1 as compared with 1.02 in Bath. The number of boys examined as compared with girls was in Bath 3,548 to 3,477, in Glossop 600 to 622.

These figures will give a fair idea of the extent of the problem as regards school children. Regarding the general population in 1919, diseases of the thyroid body caused the deaths of 39 males and 232 females. The female sex, therefore, is very much more prone to thyroidal disease than the male.

Coming now to the steps to be taken to prevent the disease, I think that as regards the school medical service the suggestion made by me in the article in *School Hygiene* should be generally adopted: "That school nurses who inspect for vermin should be specially instructed how to observe and note the thyroidal gland condition."

If this were carried out we would have roughly a quarterly survey of all the elementary school children as regards the condition of the thyroid; where the gland was noted to be enlarged or beginning to enlarge the details should be given to the school medical officer, who could see that preventive treatment was carried out. The school medical officer could then either through a clinic or by arrangement with all the general practitioners in his area have iodine therapy and other general hygienic and remedial measures employed. As the school medical service will, however, in most cases leave the child at the age of 14 years it will be necessary to arrange to cover the gap between this age and the age for national insurance; would it be possible for children who left school to be considered for the purpose of medical inspection and treatment to be still school children, and under the care of the Board of Education? This gap for many other matters as well as goitre is one that should be bridged.

On arriving at the age of national insurance the details of the defect could be handed on to the panel practitioner, who in his turn could carry treatment to a successful conclusion.

I put these suggestions forward for general consideration, and I sincerely trust it will be possible for some satisfactory arrangements to be devised whereby the population at large will reap the benefits of applied medical science.—I am, etc.,

E. H. MARCUS MILLIGAN, M.D., D.P.H.,

Glossop, July 10th.

M. O. H. Glossop and Glossopdale.

A NOTE ON THE TREATMENT OF SQUINT.

SIR,—In the issue of the *JOURNAL* of January 7th, 1922, there is a note bearing the above title by Lieut.-Colonel Henry Smith, lately of Amritsar. In that note he cites one case of divergent squint in a child in which he considered he got some relief of the squint by puncture of the supposed weak muscle and the administration of repeated faradic shocks. The real condition of the child's eyes was unknown, for he admits inability to make the necessary examination. On the strength of this one experience of a divergent squint—a type of squint notoriously variable in degree according to the health and state of nervous tension of the patient—Colonel Smith recommends us to "shake ourselves free from all that has been done" by generations of assiduous workers for the development of a rational and successful treatment of squint. The recommendation is such that I should not have troubled you with any comment if Colonel Smith had not at the same time made a specific attack upon one method of operating for squint of which I have valuable experience.

He says: "Tendon tucking . . . stretches one of the muscles of the eye and introduces a factor which cannot be gauged. From the surgical point of view any cutting operation leaves scar tissue which is subsequently liable to contract, and none is more likely to do so than tendon tucking." Tendon tucking, he adds, "almost invariably means muscle tucking." In my own experience tendon tucking is practically reserved for the lateral rectus in dealing with convergent squint. The lateral rectus has 8.8 mm. of tendon, and it is this which is tucked and not the muscle itself. No operation for squint can be gauged with precision, but Harman's reefing operation can be gauged with more precision than most. The scar tissue in this operation is minimal, and none is less likely to contract subsequently than this.

Why Colonel Smith should have a particular prejudice against the tucking or reefing operation I do not know. I have been interested in and operating on squint for over twenty years. For the last ten I have done Bishop Harman's reefing operation combined with his method of lengthening the medial rectus, almost to the exclusion of all other procedures, and I am satisfied that it is the best and most satisfactory operation in the field at present. I hope later on to publish my results, which must now run into some hundreds.—I am, etc.,

E. C. TEMPLE SMITH, F.R.C.S.E., D.O. Oxon.,

Senior Ophthalmic Surgeon to the St. Vincent's Hospital and to the Royal Alexandra Hospital for Children, Sydney, Australia.

May 23rd.

SERUM IN THE TREATMENT OF VELDT SORES.

SIR,—A few months ago a fellow medical man a day's journey off, who was suffering from veldt sores, asked me to come to his help. He wrote:

"In spite of trying every method of treatment I can think of they have not got better; indeed, they have increased both in size and numbers until now my buttocks are almost covered with these sores. I think the only rapid cure would be to have them scraped and cauterized under an anaesthetic."

On examination I found the condition had not been overstated. The only antidipltheritic serum available was 5,000 units of some old Merck's stuff, which must have been brought here by the Germans before August, 1914, and was therefore about seven years old at least.

After discussing the matter it was decided to take the risk of a failure with this old serum, and I injected 4,000 units subcutaneously in the neighborhood of the sores, using the little serum left to swab over the buttocks. The injections were received uncomplainingly, but the swabbing immediately set up an intense reaction, causing the patient to jump up and stamp up and down the room. Two weeks later he wrote:

"My veldt sores are entirely healed now. The effect of the treatment was wonderful. They commenced to improve on the third day and healed rapidly, until by the end of a week they were dry with healthy scabs on them."

There has been no recurrence, and abrasions which the patient alleges would previously have been certain to develop into veldt sores have all healed perfectly.

The chief point of interest here perhaps is that serum which had been lying about without special care for at least six years, and that in the tropics, and would not have been used at all if other serum had been available, still retained its potency.—I am, etc.,

Central East Africa, May 25th.

DAVID M. BROWN.

EFFECTS OF CHRONIC STARVATION DURING THE SIEGE OF KUT.

SIR,—The following points may be of interest to those who have read General Helier's article (June 3rd, p. 865). They were noted during the famine of 1897 in the Jubbulpore district.

Condition of the Bowels.—Specimens of the large and small intestines of patients dead of starvation were sent to the Clinical Research Association. A report was received that the glandular element had atrophied. It is probable that once the atrophy has reached a certain stage the specific structure is not again reproduced. This would account for the fact that after a certain stage of starvation has been reached recovery is impossible, even with appropriate food.

Critical Point of Starvation.—This occurred in people who were still able to stand and even walk feebly. In children it was signalled by atrophy of the buttocks. Those who showed this sign never recovered whatever their general condition was.

Unsuitable Diet.—This was the actual cause of death in a large number, probably the majority, of cases during the famine. True cholera was present throughout the famine area, but the fatal complaint in the relief camps was of a dysenteric type, not choleraic, and hopeless to treat.

Cancerum Oris.—This was a scourge amongst the children in the relief camps. It did not apparently occur amongst the adults in Kut, nor was it noted amongst the starved Turkish prisoners after the final overthrow of the Turks in Palestine and Syria in 1918.—I am, etc.,

Shillong, Assam, June 30th.

W. H. OGILVIE, M.B., D.Sc.,
Colonel I.M.S.

THE NAVAL MEDICAL SERVICE.

SIR,—In your recent article on the subject of the injustice which has been inflicted by the Admiralty on a certain group of senior surgeon commanders, R.N., you very rightly warn intending candidates for the Naval Medical Service of the treatment they may expect if they join the navy.

It does not seem to be consistent with your warning to continue to publish Admiralty advertisements for surgeon lieutenants for short service, especially as the advertisement states those officers will be considered for transfer to the permanent service under certain conditions.

Including the equipment allowances the terms offered amount to £600 per annum, and may appear reasonable; but it must be remembered that the Admiralty could have kept on the senior surgeon commander at a cost of £140 per annum—the difference between their maximum full pay of £1,040 per annum and their retired pay of £500—and at a saving to the country of £150 per annum.

I trust the Association will see its way to discontinue inserting the advertisement, which in itself does not appear to be free from criticism; the period of service is stated to be three years, with option to extend for further twelve months, and this seems to be open to a possible Admiralty interpretation that the option is theirs to keep on an officer, against his will, over the three years if he is serving on a foreign station or for other reasons, and we know from recent experience the officer would have no remedy.—I am, etc.,

London, July 16th.

A VICTIM.

TENDON TRANSPLANTATION.

SIR,—I am entirely in agreement with Mr. Fairbank when he points out in your issue of July 29th (p. 190) that in some cases in which hamstring muscles have been transplanted to the patella to replace a paralysed quadriceps some recovery has subsequently occurred in the quadriceps.

One of the cases which I demonstrated at the clinical lecture reported in your issue of July 15th showed a slight recovery in the quadriceps, as Dr. Menell, who was present, pointed out to me. I have never seen this recovery amount to anything more than a flicker of muscular contraction, and it has not been sufficient, in any case which I have seen, to produce any appreciable extension of a flexed knee.—I am, etc.,

Manchester, July 31st.

ROBERT OLLERENSHAW.

TOBACCO SMOKE AND CANCER.

SIR,—Referring to a letter on "Tobacco smoke and cancer" in your issue of July 8th, Dr. Abbe of New York, an eminent surgeon and a pioneer in the medical and surgical uses of radium and its properties, once told me he had never met with a case of malignant disease of the lips, tongue, mouth, or throat in a non-smoker or one who did not chew betel-nut or his hands.—I am, etc.,

London, W., July 16th.

C. DUBER, Lieut.-Col. I.M.S. (ret.).

BEER AND LEAD POISONING.

SIR,—Our attention has been directed to a paragraph on page 179 in your current number with regard to beer and lead poisoning. It is suggested that poisoning may result from the use of lead glaze in stoneware receptacles.

As far as we are aware, we are the only manufacturers of stoneware containers for this purpose, and no lead whatever is utilized in the glaze of these vessels. Should poisoning have resulted from beer used in such containers it cannot, therefore, be due to the reason suggested, but must arise from some other cause.

As prominence has been given to the paragraph we feel compelled, owing to the authoritative nature of your JOURNAL, to ask for a correction.—We are, etc.,

London, S.E., August 1st.

DOULTON AND CO., LTD.

** We understand that the apparatus referred to in the note last week was not made by Messrs. Doulton.

Universities and Colleges.

OXFORD AND CAMBRIDGE UNIVERSITY COMMISSIONS.
THE President of the Board of Education introduced into the House of Commons on July 24th a bill to carry into effect certain recommendations of the Royal Commission appointed to consider the applications made by the Universities of Oxford and Cambridge for financial assistance from Parliament. The Commission reported on March 24th, 1922: It conducted the greater part of its inquiry in two sections, one for Oxford and the other for Cambridge, and at each place inquired into the financial resources of the University and the colleges, the administration of these resources, the government of the University, and the relation of the University to the colleges. It advised that two statutory commissions should be appointed to carry out the changes in University and college statutes recommended by the Commissioners.

The bill now introduced constitutes two bodies of commissioners, the one for Oxford and the other for Cambridge; in each case the number of members is seven. In the Oxford Commission science, including medicine, is represented by Sir Archibald Garrod, K.C.M.G., M.D., F.R.S., Regius Professor of Medicine; in the Cambridge Commission by Sir Richard Glazebrook, K.C.B., D.Sc., F.R.S., formerly Director of the National Physical Laboratory, and Sir Hugh Kerr Anderson, M.D., F.R.S., formerly lecturer on physiology in the University and now Master of Gonville and Caius College. The bill proposes that the powers of the Commissioners shall continue in force until the end of 1924, though the period may be extended by the King in Council to the end of 1926.

The duty of the Commissioners in each case will be to make statutes and regulations for the University, its colleges and halls, and any other institutions in or connected with the University; and also with regard to emoluments, endowments, trusts, foundations, gifts, and offices. The statutes and regulations are to be made in accordance with the recommendations of the Royal Commission, but with such modifications as may, after the consideration of any representations made to the Commission, appear to it expedient. After the expiration of the powers of the Commissioners the universities and colleges will resume their normal powers of government. The statutes now to be established may be altered by statutes made by the universities, but in the case of statutes which affect a college only with the consent of the college. With the permission of the Privy Council colleges also may alter their statutes. It will be remembered that the Cambridge committee of the Royal Commission recommended that women should be admitted on the same conditions as men to membership of the University, but with certain limitations. This matter will therefore have to be considered by the Commission now proposed to be established.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

THE following awards of medical scholarships and exhibitions have been made at University College, London: Bucknill scholarship of the value of 135 guineas, to R. L. Midgley. Medical entrance exhibitions of the value of 55 guineas each to E. H. Madge and V. Freeman.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.

The following scholarships and prizes have been awarded:

First Prize (divided): W. R. F. Collis, W. I. Daggett. Senior Scholarship (divided): N. W. Snell and Miss C. P. Francis. Jelf Medal and Tanner Prize: L. Dulake. Todd Prize (divided): L. Dulake and Miss C. P. Francis. Class Prizes—Diseases of Children, Miss E. C. N. Paterson, D. Davidson (proxime accessit); Orthopaedic Surgery, N. W. Snell; Medicine, L. Dulake; Surgery, W. P. Sheldon; Pathology, C. R. Lane; Obstetric Medicine, P. B. Atkinson; Forensic Medicine, A. C. T. Perkins; Hygiene, A. C. T. Perkins; Psychological Medicine, E. B. Strauss.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

The following scholarships have been awarded for session 1922-23:

Sir Owen Roberts's Memorial Scholarship: Miss D. Stewart (London School of Medicine for Women). St. Dunstan's Medical Exhibition: Miss M. H. Lester (Christ's Hospital). Mabel Sharrman-Crawford Scholarship: Miss H. Newman (London School of Medicine for Women). Isabel Thorne Scholarship: Miss E. L. Hutton (Clergy Daughters' School, Casterton). Ellen Walker Bursary: Miss V. A. Roberts (London School of Medicine for Women). Fanny Butler Scholarship: Miss E. M. Oswald (Udgate College, Wimbledon).

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary comitia of the Royal College of Physicians of London was held on July 27th, the chair being occupied by Dr. Raymond Crawford, the senior Censor, in the absence of the President.

On the report of the Censors Board, and in accordance with By-law xix, it was resolved:

1. That William Henry Starkie be declared to be no longer a licentiate of the College; that he forfeit all the rights and privileges of a licentiate; and that his name be expunged from the list of licentiates—during the pleasure of the College.
2. That John William Kynaston be declared to be no longer a licentiate of the College; that he forfeit all rights and privileges of a licentiate; and that his name be expunged from the list of licentiates during the pleasure of the College; but that an application for restoration of his licence may be considered in two years from the date of the withdrawal thereof.

The following candidates were admitted Members:

Cyril Carlyle Beatty, M.D., F.R.C.P., Harold E. A. Boldero, M.D., Oxon., D.R.C.P., Norman Brandon, Capon, M.D., L.R.C.P., Cunningham, M.D., Edin., Jeanne Conway Davies, L.R.C.P., Oliver Charles Minty, M.D., Bristol, Wm. Stovell Goss, M.B.Camb., L.R.C.P., Charles H. Kellaway, M.D., Mch., Christopher Amrita Shanta, M.B.Calcutta, Jehanir M. Munchershaw Surveor, M.B.Calcutta, John Edwin Mackenzie Wiggley, M.B.Mch., Harry George Everard Williams, M.D.Camb., L.R.C.P., Frederick Edward Saxby Willis, M.B.Lond., L.R.C.P.

Licences to practise Physic were granted to 115 candidates:

Licences.

S. Adler, N. A. Alengar, J. V. D. Allin, G. W. Ballance, F. H. Bodman, P. W. Boobyer, H. W. Briggs, G. L. Brockhurst, *Gwendolen M. Brown, R. C. Brown, *Glady's L. Buckley, N. L. Caponer, *Madeleine H. Clarke, E. A. Coldrey, L. B. Cole, R. H. Cooke, D. C. Corry, N. McL. Craig, P. P. Dalton, K. A. Daruklanavala, W. A. Dale, T. H. R. Davy, F. P. De la, H. K. Denham, J. B. Devine, C. J. Donelan, L. Dulake, *Helen W. Duncan, *Beatrice E. Eldon, *Mary G. Elliot, D. C. Fairhair, L. S. Fallis, A. R. Fax, *Christine P. Francis, W. F. Francis, C. B. S. Fuller, *Ada Furniss, H. J. J. Garrod, *Marie L. P. Goetze, *Alice M. F. Goldmann, S. Gordon, R. H. White, H. G. Hall, B. O. Hancock, T. H. J. Hargreaves, *Muriel M. Harris, S. G. Harrison, P. R. Have, *Hilda M. Haythornthwaite, E. C. Heap, M. M. Hegab, H. C. Hill, G. H. Hoeben, J. P. Hosford, E. G. Housden, G. H. Howells, J. S. Hudson, E. N. Hughes, J. Jackson, A. E. Jenkins, A. J. Nathan, J. Noss-Walker, F. G. Nicholas, L. F. O'Shaughnessy, H. M. Palmer, D. H. Patey, F. Y. Pearson, R. C. Poate, G. P. Potrowski, W. M. Ramlen, H. E. K. Reynolds, H. Richards, *Constance E. Ridout, F. D. Rieley, B. C. de S. Rupasingha, *Glady's M. Sandes, *Norah B. A. Sankar, Margaret C. Scence, C. F. H. Sergeant, N. F. Shaw, *Patricia H. S. Shaw, C. M. Short, J. Shulman, N. W. Snell, J. A. Stunters, C. Sturton, F. B. Sudbury, M. H. Summers, D. B. Sutton, H. W. Taylor, H. R. J. Thomas, T. M. Thomas, H. K. Tucker, H. D. A. Uddjian, R. H. Wade, H. K. Wallace, J. W. Wibby, *Catherine M. Williams, C. P. Wilson, G. Wilson, D. A. Windenr, J. A. Young.

* Under the Medical Act, 1875.

Diplomas.

Diplomas in the subjects indicated were granted in conjunction with the Royal College of Surgeons to the following candidates:

PUBLIC HEALTH.—J. E. Rowen, D. S. Brachman, B. C. Dasgupta, P. Davis, A. M. El-Kirdany, R. P. Fagan, C. H. H. Harold, P. A. Harvey, E. B. Hobbs, C. B. Hogg, A. E. Ionside, Doris E. P. Jolly, R. L. Joshi, G. J. W. McMichael, M. C. Madhoc, J. Misquitta, W. Oats, G. R. Panton, Barbara Richardson, J. P. Rosh, A. D. Soares, Ruth C. Townshend, J. R. D. Webb, H. G. Wiltshire, F. H. Young.

TROPICAL MEDICINE AND HYGIENE.—B. F. Beaton, H. C. Berlie Nancy E. Bleakley, C. V. Boland, D. I. Cameron, V. M. Fisher, P. Gupta, S. Hunt, H. S. Lucraft, G. S. Marshall, L. M. Moody, E. R. K. Iersborger, M. Schwartz, M. Theiler, S. M. Vassallo, M. Jacob, Margaret H. R. Young.

OPHTHALMIC MEDICINE AND SURGERY.—D. P. Bhargava, J. C. Bharcha, R. E. Collins, E. MacA, G. Glassford, R. McMe, G. N. Mea, G. R. A. J. Kapsi, K. E. Madan, Glady's H. Marchant, J. S. Monro, R. H. Saurat, C. O. M. Alley, S. Coulter, J. D. Twigg.

PSYCHOLOGICAL MEDICINE.—J. Hestock, J. J. Gasperine, H. H. P. Norton, N. Navarra, F. N. Noronha, F. Paine, E. C. Itayuer, C. D. L. Rixon, K. M. Rodger.

The Examiners for the Murchison Memorial Scholarship reported that Arthur Henry Douthwaite and Charles Frederick Terence East were equally deserving of the Scholarship.

College officers, members of committees, and examiners for the ensuing year were elected on the nomination of the President, Council, and Library Committee:

Censors.

Raymond H. P. Crawford, M.D., Horace George Thorne, O.B.E., M.D., Herbert Morley Fletcher, M.D., Bertrand Edward Baron Dawson of Penn, G.C.V.O., K.C.M.G., C.B., M.D.

Examiners.

Chemistry.—William Bradshaw Tuck, D.Sc., Charles Stanley Gibson, O.B.E., B.Sc., F.C.
Physics.—Frederick Womack, M.B., B.Sc., Alfred Henry Fison, D.Sc.
Practical Pharmacy.—Alfred Ernest Russell, M.D., Edward Alfred Cockayne, M.D., Philip Hamill, M.D., Alfred Joseph Clark, M.C., M.D., Walter Ernest Dixon, O.B.E., M.D.
Physiology.—John Borsford Leathes, M.B., John Mellanby, M.D.
Anatomy.—Thomas Baillie Johnson, M.B.
Medical Anatomy and Principles and Practice of Medicine.—William Aldron Turner, C.B., M.D., Herbert Morley Fletcher, M.D., John Walter Carr, C.B.E., M.D., Joseph John Perkins, M.B., Arthur Philip Beddard, M.D., Arthur John Hall, M.D., Sir James Purves Stewart, K.C.M.G., C.B., M.D., Robert A. Young, C.B.E., M.D., Charles Bolton, C.B.E., M.D., Sir William Henry Willcox, C.B., C.M.G., M.D.
Midwifery and Diseases Peculiar to Women.—John Prescott Hootley, M.B., Ewen John Maclean, M.D., Thomas George Stevens, M.D., John Davis Barris, M.B., Harold Chapple, M.B., F.R.C.S.
Public Health.—Part I: Henry Wilson Hake, Ph.D.; Part II: David Samuel Davior, M.D.
Tropical Medicine.—John C. Grant Ledingham, M.B. (Bacteriology), John Brian Christopherson, C.B.E., M.D. (Diseases and Hygiene of the Tropics).
Ophthalmic Medicine and Surgery.—Gordon Morgan Holmes, C.M.G., C.B.E., M.D.
Psychological Medicine.—Part I: Henry Devine, O.B.E., M.D.; Part II: James Taylor, C.B.E., M.D., Charles Herbert Bond, C.B.E., M.D.

Dr. Lauriston Shaw was appointed a councillor in the place of the late Dr. W. H. R. Rivers. At the request of the Royal Society of British Architects Dr. Dawtry Drewitt was appointed representative of the college on a committee to consider the commemoration of the bicentenary of the death of Sir Christopher Wren. Sir Arthur Keith was given permission to photograph the portrait of Sir Thomas Browne in the possession of the college. At the request of Mr. Holman Wilson the college agreed to help in re-erecting in the church of St. Leonard's, Exeter, certain panels which formed part of the altar tomb of Dr. William Musgrave, F.R.C.P., F.R.S. Mr. T. J. C. Tomlin, K.C., was appointed senior standing counsel to the college. A report from the Censors Board concerning the Lloyd Robert Lectureship was referred to the college lawyers. The membership which Dr. R. A. Chisolm resigned in 1919 was restored to him. Sir William Church and Sir Thomas Barlow were reappointed members of the Executive Committee of the Imperial Cancer Research Fund, on the nomination of that committee, and Sir Frederick Andrews was re-appointed a representative on the same committee.

A report was received from the representatives of the two Royal Colleges on the International Congress of Ophthalmology, held at Washington in April last. (Mr. E. Treacher Collins, F.R.C.S.) An invitation to hold the next congress in London in 1925 was accepted. After some formal business the comitia was dissolved.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary council was held on July 27th, when Sir Anthony Bowlby, President, was in the chair.

Diplomas.

Diplomas of membership were granted to 113 candidates found qualified at the recent examinations. The Diploma in Tropical Medicine and Hygiene was granted to 17 candidates (jointly with the Royal College of Physicians) recently found qualified. The Diploma in Ophthalmic Medicine and Surgery was granted to 14 candidates found qualified (in conjunction with the Royal College of Physicians).

Examiners.

Mr. F. F. Burglard was re-elected a member of the Court of Examiners, and Dr. I. Lewin Payne was elected a member of the Board of Examiners in Dental Surgery.

Imperial Cancer Research Fund.

Sir William Church and Sir Thomas Barlow were re-elected members of the Executive Committee of the Imperial Cancer Research Fund.

CONJOINT BOARD IN ENGLAND.

Forensic Medicine.

THE synopsis of forensic medicine has been revised by the Committee of Management of the Conjoint Board in England, and has now been adopted both by the Royal College of Physicians of London and the Royal College of Surgeons of England. It is as follows:

Privileges and obligations of medical practitioners. Medical registration. Medical certificates and notifications. Medical evidence. Dying declarations. Procedure relating to coroners' inquests. Signs of death and the phenomena which follow death. Putrefaction in air. Putrefaction in water. Mummification. Formation of adipocere. Inspection of the dead body and post-mortem examination. Medico-legal aspects of identification. Modes of death. Causes of sudden death. Death from the following causes: Wounds and mechanical injuries. Hanging. Strangulation. Suffocation. Drowning. Electrical current and lightning. Starvation. Indications of death from accident, suicide, or homicide. Methods of recognition of blood stains.

Poisoning.—Medico-legal duties of medical practitioners in cases of poisoning. Symptoms and post-mortem appearances produced by the common inorganic, organic, and gaseous poisons, and the treatment of the patient.

Method of post-mortem examination in cases of poisoning, and reservation of parts of the body for analysis.

Causes and treatment of poisons. The sale of poisons.

Legal aspects relating to pregnancy, delivery, rape, criminal

as far as they affect the medical practitioner in

of certificates of lunacy.

Obituary.

THE LATE SIR EDWARD MALINS.

DR. THOMAS WILSON (Birmingham) has been good enough to send the following appreciation of his late colleague and friend:

Thirty years ago when I became his junior colleague at the old General Hospital Malins had already been in practice in Birmingham for twenty years, and his name was a household word in the city and a large surrounding district. I was at once impressed by the constant and punctual discharge of his hospital duties, and by his devotion to, and sympathetic interest in, his patients, as well as by his knowledge and skill. His patients looked up to him with esteem and respect, and returned his care with real affection. In the students he took a close and kindly interest, and to his colleagues, and especially the juniors, he was ever considerate and loyal. When illness or misfortune overtook those who had worked with him his ready sympathy, and when needed his generous help, were unobtrusively given. He became a specialist after a long and arduous general training, first by apprenticeship, then by the usual course in the University of Edinburgh, and afterwards by some years in busy general practice. Before leaving Edinburgh he had become assistant to Sir James Simpson, and so had acquired a sound practical acquaintance with the principles of midwifery and diseases of women. Through the whole of his life his mind remained open to new ideas, and he earnestly and successfully strove to keep abreast of advances in knowledge and practice as the specialty developed from the era of mechanical pathology and pessaries to that of surgical and more modern scientific methods.

As Professor in the University Sir Edward Malins took the greatest pains to keep his teaching on the highest and most advanced level, was most assiduous and punctual in the discharge of his duties, and possessed the esteem and regard of the students to a marked degree. As an examiner of students and nurses he was judicial and impartial, patient and considerate. He devoted a large part of his life to the service of the General Hospital and of the University, taking a profound interest in both and giving to them of his best. Outside his professional work he had many interests. A devoted and hard-working churchman, he practised his religion unobtrusively in his daily life. In political and social matters he took an active interest, and of general literature he was a diligent and widely read student. At the University Graduates' Club, of which he was twice President, he was a regular attendant, and was esteemed one of the most valued and interesting speakers. In daily intercourse he bore himself with quiet and unassuming courtesy: 'To him came many honours, unsought, modestly accepted, and sustained with dignity. Among them, the most welcome to his local brethren and I think to himself, was the highest in the power of the members of his specialty to bestow—the Presidency of the London Obstetrical Society, to which office he was the first provincial member to be elected. His presence and example will be missed in many circles, and in none more than in that of the brethren of his specialty. By them he was honoured and esteemed, and among them his place will not readily be filled.

Sir FRANCIS CHAMPNEYS writes:

The obituary notice of Sir Edward Malins, accurate as it doubtless is on matters of history, lacks the personal note which should give life to a biography. The fact that he had attained the advanced age of 80 is probably accountable for this. But there are some who remember their association with him in active work. Sir Edward was a very old member of the Obstetrical Society, and it must be forty years since I was first associated with him at that society, which has now become the Obstetrical and Gynaecological Section of the Royal Society of Medicine. He was, I think, the first provincial Fellow to become its president, and he discharged his duties remarkably well. His characteristics, indeed, were

dignity, courtesy, firmness, sound judgment, uprightness, and public spirit. It was always a pleasure to work with him. He leaves the memory of a long and very useful life behind him, and he rests from his labours.

THE death is announced of Dr. GAVIN STELL of Clapham, who was one of the best known medical practitioners in south London. Dr. Stell was born in 1857, and was educated at Dunfermline High School and Edinburgh University; he graduated M.B., C.M. in 1881, and M.D. in 1897. After holding various appointments he settled in Clapham in 1887 and built up there a very large general practice. He kept himself well abreast of recent developments in medicine and surgery, and his sympathetic and kindly nature, with his unceasing care and devotion to his work, gained him the affection and esteem of all with whom he came in contact. He was an old member of the British Medical Association and one of the original Fellows of the British Balaenological and Climatological Society, of which he remained a member until its amalgamation with the Royal Society of Medicine, of which he was also a Fellow. He is survived by his widow and two sons, both of whom have adopted the medical profession, the elder practising in Clapham in association with his father, and the other in Lincoln.

Medical News.

FOR the Ladies' Golf Competition in connexion with the Annual Meeting of the British Medical Association at Glasgow there were sixteen entries, but owing to the inclemency of the weather only eleven actually played. Miss Robertson, Elioeh Lodge, Prestwick, won the prize for the best round; Mrs. Lamb, Mount Annan Drive, Mount Florida, won the prize for the hidden holes. The prizes were the gift of Mr. William Rankin.

MAJOR-GENERAL C. E. POLLOCK, C.B., C.B.E., D.S.O., late R.A.M.C., has been appointed Deputy Director-General, Army Medical Services, vice Major-General Sir George B. Stanistreet, K.B.E., C.B., C.M.G., late R.A.M.C.

THE National Health Society, in compliance with the alteration made in the Regulations of the Board of Education for the training of health visitors, is arranging a shortened course of training for qualified nurses and health visitors of three years' service under local authorities. The next course commences in September. Particulars may be obtained from the secretary, 53, Berners Street, W.1.

A CONFERENCE on the disposal of London refuse was held at the Ministry of Health at the end of June, and the Minister has now issued a memorandum covering a poster detailing the precautions which should be taken, not only in London but elsewhere, in managing refuse tips to prevent the causation of nuisance. The principal precautions recommended are that the refuse should be deposited in shallow layers, and that each layer should be promptly covered with earth or other suitable material to prevent nuisance from fire, rats, flies, or smells.

AT the suggestion of the Medical Director the Health Committee of the League of Nations Union has invited certain Governments to nominate commissions of some four or five public health medical officers to spend three months working in the health administrations of other countries.

AT the June matriculation examination of the University of London there were 169 successful candidates in the first division and 1,258 in the second division, while 36 secured the supplementary certificate for Latin.

THE summer general meeting of the Irish Medical Schools' and Graduates' Association was held in the Grand Hotel, Glasgow, on July 24th, the President, Dr. J. A. Macdonald, LL.D., in the chair. Forty-eight members and their friends had previously had lunch together, when the President said he had much pleasure in announcing that the number of new members enrolled during the previous twelve months was the largest recorded in any similar period in the history of the association, extending over forty-four years. He quite anticipated that the total number on the roll by the time his year of office had expired (next St. Patrick's Day) would be fully a thousand. When this total was reached they would be in a position to resume the "monopoly" fight, which in days gone by had been so successful. It would not be long, he (the chairman) felt sure, before the English lovers of justice would cause the barriers to be removed which now prevented the Fellows of Irish and Scottish Colleges from even becoming candidates for positions on the honorary staffs of general

hospitals in England. The toast of the King's health having been very heartily received, that of the Guests was proposed by Dr. James Stewart and responded to by Dr. Agnes Estcourt-Oswald, whereupon the meeting adjourned.

THE Board of Education has issued a pamphlet (price 3d. net) giving a list of institutions recognized by the Board under regulations for nursery schools, the training of health visitors, and the training of midwives; and a revised list of institutions for the welfare of the blind and of defective and epileptic children.

A CHRISTIAN Science practitioner was found guilty recently, in the municipal court of Cleveland, Ohio, of practising medicine without a licence, and was fined 100 dols. and costs.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

notice to be taken of their communications with their names—of course not.

Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Littology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

"MEDICO" recently purchased a practice, and claimed £45 for expense of drugs purchased on taking over. This has been disallowed as capital outlay.

*. The amount allowable is the cost of the drugs consumed in the year's work, and the cost of the total stock taken over is part of the cost of the practice as a whole and inadmissible for tax purposes.

G. K. inquires whether he is correct in assuming that "flat-rate remuneration, National Health Insurance fees, and Parish Council salary are still assessable under Schedule D."

*. The last mentioned is technically assessable Schedule E, but the other two appear not to be profits of "employment" and consequently assessable Schedule D. If these two considerably outweigh the other source of income we conceive that the authorities would continue the practice of pooling the whole in one Schedule D assessment.

F. A. A. sold a 1916 Overland Coupé 20-25 h.p. and bought a 1922 Rover 12 h.p. The latter car cost £200 more than the old car did, the net cost of the renewal being £425. The inspector of taxes refuses to allow more than £325 on the ground that £100 or more was expended on improvement.

*. The amount allowable is the 1922 cost of a 20-25 h.p. Coupé Overland less £225 received for the old car. On this basis the inspector's action seems justified.

WARTS OF THE SCALP.

X. Y. Z. would be glad to hear of a satisfactory treatment of warts of the scalp. Snipping and the canthary have been tried without benefit, but treatment is hampered by the risk of losing the hair.

*. Warts of the scalp usually yield readily to an application of radium.

RELIEF OF PAIN IN ACRONEGALY.

DR. J. H. DOUGLAS WEBSTER (London) writes in reply to Dr. W. Gover (Hastings), who inquired how the intolerable pain in acromegaly could be relieved: X-ray treatment often gives speedy relief to the symptoms—headache, contraction of visual fields, etc. I have published a case, and others have recorded

similar good effects from x-ray treatment. At the Scandinavian Radiological Congress in Copenhagen last year many good results were reported, in cases of intracranial tumours, from radium therapy.

LETTERS, NOTES, ETC.

A "SERIOUS CASE."

DR. W. JOHNSON SMYTH (Bournemouth) writes: Acutely apprehensive of only a brief span of life a lady consulted me lately and explained that a specialist recently discovered that she suffered from an "impalpable spleen" and that he took a very serious view of her ailment. I corroborated the specialist's discovery, prescribed a rich diet and a few noisy electrical remedies with which she was not familiar. Her recovery was rapid.

HOSPITAL v. ASYLUM.

DR. S. E. WHITE (London, E.) writes: The hospitalization of asylums is in the air. No lovelier thing could be devised than to remove the shadow that broods over asylum life; to give light to them that sit in darkness, and to introduce into that dim forsaken land methods by which the heart is cheered and health restored. Professor G. M. Robertson proclaims: "Let there be no more prison atmosphere! We do not call in a magistrate to sanction admission into a hospital." True, but the patient can in this case discharge himself. Does the professor intend that no greater measure of detention shall in the future be exercised over the unbalanced than prevails in hospitals for bodily disease? He can hardly mean that. He has a plan whereby those who enter voluntarily can be detained for six months or medical authority alone—the arrangements being strongly commended by the fact that there will be "no certification"—that means, no provision for any judicial intervention or appeal. This proposal is naturally accepted readily by those who keep asylums. But no roseate picture of the delights of hospitalized asylums can reconcile most people to the loss of liberty. The sense of the rights of the subject has entrenched itself so firmly behind English law that psychiatrists find it no easy matter to drive it out. Five times since 1903 the Lunacy Commission has essayed to pass this measure through Parliament, but without avail. The sense of fair play has been too strong. Fain would the Board of Control gather under its wing all early cases to detain them for their good; but the early cases refuse to flock to it. The Board is not at all satisfied with its function of looking after the certified—that is, the helpless whom they are supposed to protect—but would willingly find "half-way houses" for all those who are on the way to being certified. There exist at the present moment all over our land huge institutions into which are gathered a heterogeneous mass of people. Some of these indubitably require restraint, but an equally large number are housed therein who would recover much more speedily if invited to appropriately equipped cheerful sanatoriums and spared this iron rule. There ought to be called into being some suitable alternatives to asylums. It is a crying need. But the new hostels must be hospitals in fact, not semi-asylums. Once liberty is interfered with, it is all-essential that, to prevent injustice, something in the nature of an inquiry must be held; the "alleged lunatic" ought to be told what is being alleged, and be permitted to defend himself. This is only fair. As things are at present, everything is done in secret; and according to the proposals now issuing from the Health Ministry the proceedings are likely to become still more subterranean. This is a retrograde step. No measure of the kind is needed. No legislative barrier stands in the way of running hospitals without detention. Before committing a man to an asylum, he ought to be proved to be dangerous and unfit to be at large. For all others, the true hope of the future lies in the starting of real hospitals with reassuring atmosphere and free access to the air and light of heaven.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 27, 30, 31, and 32 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenures at pages 28 and 29.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 84.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	s.	d.	
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

All remittances to the British Medical Journal must be made payable to the Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

WHY DUNLOP CORD TYRES ARE BETTER TYRES

This illustration shows the construction of the DUNLOP beaded-edge CORD TYRE.

1. Larger air space.
2. Dunlop multiple ply cord fabric.
3. Pure rubber insulation between each layer of fabric.
4. Shows cord layers in opposite directions.
5. Improved bead design.
6. Breaker strips.
7. Heavy non-skid tread.

The main advantage of this cover over the canvas pattern lies in the construction of the casing.

ITS CONSTRUCTION AND ADVANTAGES.

The constructional method practically eliminates destructive internal heating. Friction between the materials is considerably reduced by the arrangement of the layers of straight cords diagonally across each other, with insulating plies of pure rubber interposed between them. All overlapping and thickened joins are in this way eliminated. The life of the tyre is hugely increased, and petrol consumption considerably reduced. In addition, increased resiliency is secured, which, combined with the extra size as compared with canvas tyres, means more comfort and reduced maintenance cost.

Row, BIRMINGHAM,

THE DUNLOP CORD TYRE IS THE "NO-TROUBLE" TYRE.

THE DOCTOR'S IDEAL CAR

A new 3 seater body suitable for all chassis and specially designed to suit the especial needs of all medical men.

Cars complete with these bodies:—

11.9 H.P. Morris-Cowley £450
 11.9 H.P. Bean ... £505
 18 H.P. Buick ... £520
 10.15 H.P. Fiat ... £595

12 H.P. Austin ... £635
 13.9 H.P. Standard... £635
 11.4 H.P. Humber ... £685

EARLY DELIVERIES
 DEFERRED PAYMENTS
 EXPERT ADVICE
 BODIES for all CHASSIS

Offord & Sons, Ltd.

Established over a century.
 67, George Street, Portman Square, W. 1.
 Telephone: 99 Paddington. Telegrams: "Deafis. London."
 AND AT SOUTH KENSINGTON.

PRICE OF
 BODY ONLY £185

Write for full prices,
 illustrations, etc.

The Popular Lecture

ON

THE PHYSICIAN: NATURALIST, TEACHER,
BENEFACITOR.DELIVERED TO THE BRITISH MEDICAL ASSOCIATION AT
GLASGOW ON JULY 28TH,

BY

J. GRAHAM KERR, M.A., F.R.S.,

REGIUS PROFESSOR OF ZOOLOGY IN THE UNIVERSITY OF GLASGOW.

SOME years ago at a dinner in this city I was called upon to propose the health of a distinguished company of physicians, and in doing so I recalled an incident that happened long ago during one of my early expeditions in South America. I had arrived in the country of a tribe of primitive red men and was engaged in the preliminary work of getting our relations on a satisfactory basis. One day I found myself traversing one of the great swamps of the region alone with one of the most potent members of the tribe. We arrived at a particular spot, and he indicated that he would fish: he bent the swamp vegetation out of the way so as to make a little clear pool a foot or two in diameter; then he baited his hook and patiently waited for the fish to nose their way into the pool through the surrounding vegetation. There we remained for an hour or two in silence, he from time to time pulling out a fish, while each of us regarded critically the other, sizing one another up, as the slang expression has it. And as we communed together—that naked red-skinned savage and I, a callow graduate of Cambridge—there gradually crept across my mind the thought that there beside me was a fossil man—a living fossil—the medicine man of the tribe, the evolutionary ancestor of our two professions, that of the naturalist and that of the physician, and of the priest by the way as well.

That after-dinner speech had—as perhaps most of my after-dinner speeches have not—a good effect, for one of the subsequent speakers made known to me that charming and scholarly address entitled, "The Physician as Naturalist," delivered by Sir William Gairdner when President of the British Medical Association in 1888. Indirectly, too, it was the cause, when I had the honour of being invited to deliver to-night's lecture, of my choice of title.

What I propose to do, then, is to glance at the physician in his rôle as a citizen of our community and to say something about three different aspects of him and his work—that of the naturalist, that of the teacher, and that of the benefactor.

THE PHYSICIAN AS NATURALIST.

The professional biologist or naturalist (I use the two words as synonyms) has necessarily a strong fellow-feeling with those who follow the profession of medicine, for in these days it is generally true that every year it becomes more definitely a branch of applied biology, is the one great learned profession in which it is officially recognized that a training in the elements of biology, and an elementary knowledge of the methods and principles of that science, must lie at the foundation of professional training if that foundation is to be well and truly laid. And it is extraordinarily fascinating to watch the evolution of medical science, and see how more and more its problems become recognized as problems of natural history.

Take the general mechanism of the body. We see it in its simplest form away down in the protozoa of freshwater pools—single cells leading a solitary existence, or it may be attached to one another in little groups that blunder about in their watery environment. As evolution proceeds, bigger and bigger groups of these cells remain attached together, but as the cell community increases in size its movements become more precise, its activities more definite: it develops more and more strongly an individuality of its own. It evolves at length into one of those marvellous cell communities exemplified by the body of one of the more complex animals, such as a butterfly, a bird, or a man.

How does such an individual compare with the simple protozoan individual? In the first place, it is composed of an enormously greater number of cell individuals. In the second place, these cell individuals are no longer all alike; they have become specialized for different functions—some to form a rigid supporting skeleton, some to form muscles to move the parts of the skeleton on one another and so to

bring about movements of the body as a whole, some to absorb food or oxygen, or to get rid of poisonous waste materials. In the third place, the enormously increased size of the cell community renders it necessary to have a special co-ordinating mechanism to knit the whole together into a coherent individuality—the nervous system. And, lastly, there is a point which is very usually overlooked—the primitive protozoan was aquatic; its surface was bathed directly by the water in which it lived. I said water, but of course it is not water in the precise chemical sense of the word. Water—pure water—is a substance which no one has ever seen. If it could be produced it would not remain for an instant of time; other substances instantly dissolve in it. If it falls as a drop of rain the gases of the atmosphere pass into it; if it trickles on the ground it dissolves other material as it goes. What we call water, then, in ordinary life is really a dilute watery solution of many different substances.

Now, as the animal body has proceeded along its evolutionary path, the majority of the cells composing it have become shut away from the external medium; it may be, as in the case of the butterfly or the man, that that external medium is no longer water but air. But yet we find that the cells of the body are still leading their ancient aquatic existence, for the body has enclosed within it a certain amount of water—what was called the internal medium by the great French physiologist Claude Bernard—and this bathes the surface of every constituent cell. The ancestral watery pool was affected in composition by its living inhabitants, the more so the more crowded they were; they absorbed from the water oxygen and food material, while, on the other hand, they discharged into it the various waste products of their bodies, both food material and waste products being liable to differ according to the particular type of creature. And so also with the internal medium of the body. It bathes the surface of the myriad members of the cell community. Each takes from it the food that it needs for its special activities; each discharges into it the particular waste substances which happen to be the product of its own peculiar activities.

It follows, then, that the internal medium of the body is a fluid of extreme, although ordered, complexity, and the cell individuals are adapted to live in a medium of this particular complexity, just as one animal is adapted to live in fresh water and another in salt. The composition does not remain absolutely without change—nothing does in the living body—it is liable to alteration from time to time, as one or other type of its cell inhabitants is more or less active in what it discharges into it or takes away from it. And these little fluctuations in the composition of the internal medium are actually made use of in the normal activities of the body: they set going the appropriate reactions of the body necessary to meet the ordinary contingencies of life—for example, if the proportion of carbon dioxide becomes increased by ever so little it at once serves as a danger signal to the respiratory centre in the brain, and this instantly causes the breathing movements to be accelerated; or again, a little change in composition which normally follows the taking in of food at once brings about formation of the necessary digestive juices. While the reactions to these commonly occurring little changes in the composition of the internal medium form part of the ordinary life of the individual it is otherwise when changes of greater amplitude occur. Then uncomfortable, and it may be disastrous, effects are produced on the cell inhabitants, and the condition becomes pathological in place of physiological; it may be that all members of the cell community, alike are affected, but more usually the ill effect will vary in different parts or different tissues of the body, according as the particular set of cell individuals is more or less exposed to the influence of the internal medium, or, on the other hand, more or less sensitive to the particular change that has taken place.

The modern physician, however, has come to be interested not merely in the natural history of the body of man in itself. He has been given cause to interest himself in the biological relations of man with the other living organisms of the world around him, for these relations affect in the most intimate way the health of mankind. How better could I illustrate this than by the familiar case of malaria? Reckoned in its direct and indirect effects the most destructive of all diseases, it has been estimated to cause one-half of the entire mortality of the human race. It is only a comparatively few years ago that the method to be adopted to combat malaria formed one of the most insistent problems confronting medical science.

I had the curiosity to look up the article "Malaria" in the ninth edition of the *Encyclopædia Britannica* to refresh my

memory as to how this problem was regarded in the days immediately preceding the time when it found its solution as a problem of natural history, and this is what I read:

"The most prevalent hypothesis of malaria is that it is a specific poison generated in the soil. Perhaps not every soil is capable, under circumstances, of causing malaria, but it is difficult to assign limits to its potential presence. There are seemingly well-authenticated cases of malarial disease appearing during the making of railway cuttings, canals, and other excavations, in places where malaria had not previously been known; and there is sufficient evidence that malaria has appeared in the track of cultivation in the Western States of America, and that it follows the upturning of virgin soil, and even of soil that has been long a malarious poison from the gas generated by swamps, or from the air of malarious localities. Still more attempts have been made to discover the hypothetical poison among the numerous minute vegetable organisms that occur in the soil. . . . Another hypothesis is that malaria is a 'telluric intoxication,' generated by the vegetable power of the soil when that power is not duly exhausted by plant growth. Lastly, there is an hypothesis that malarial fevers are caused by the excessive and sudden abstraction of heat from the body under the influence of cold and damp. . . ."

Does it not seem incredible that these words, fairly representative of the views regarding the malaria problem that were current as late as the "eighties" and "nineties"—blind gropings without a suspicion as to the true solution?

How different to day: the problem solved in almost every detail—so that there is no disease which medical science can combat more effectively than malaria. And how has all this come about? Because the malaria problem came to be tackled as a problem in natural history. As you all know, it turns out that malaria is a possession not of man alone, but of a dual partnership—man and a particular type of mosquito. Man catches the disease from the mosquito; the mosquito catches it from man. If man were exterminated in a particular locality it would conduce to the health of the local mosquitoes: they could no longer catch malaria. If, on the other hand, the anopheline mosquitoes were exterminated from a particular locality, then the human inhabitants could no longer catch malaria. In the solution of the details of the problem many workers were concerned, but the all-important part—the demonstration of the relationship between the malaria type of microbe and the mosquito—was the work of our own countryman Ronald Ross, and it was that demonstration that pointed the way to the anti-mosquito campaigns by which Ross and his followers have been able to diminish, or even to clear out entirely, malarial disease in many of the most deadly spots in the warmer regions of the world.

I have mentioned malaria because it affords an extraordinarily striking case of a medical problem finding its solution along the lines of natural history. There are many other cases similar in nature, though less impressive in the scale of size. To us in Scotland naturally occur in this connexion the names of David Bruce and William Leishman, and of their younger followers such as Leiper and Muriel Robertson.

Instead of taking the case of a specific disease like malaria I might very well have taken some of the more general processes of the body in which medicine interests itself, such as, for example, the general protective mechanism of the body against microbes. As we have seen, the body consists of a cell community or cell republic. Its constituent cells are protected from the assaults of alien and hostile cells by their enclosure within an elaborate defensive envelope, the skin. Certain types of microbe, however, possess the power of making their way through the skin, while in any case the skin is liable to be breached by accident, the way being thus opened to hostile invasion.

It follows, then, that the cell republic of the body requires internal defensive arrangements to deal with invaders that have passed the outer defences, and the investigation of these defensive arrangements admittedly constitutes one of the most important chapters in modern medicine, associated as it has been with immensely important practical developments in the science of healing. But they also constitute one of the most fascinating chapters in modern biology, and perhaps the name to which posterity will accord the highest position in the history of these developments is that of a professional zoologist, Metchnikoff. In his early days Metchnikoff had worked at the embryology of a great variety of the lower types of animal and published a large mass of important embryological work. In various of these simply organized creatures, on which Metchnikoff worked, he came across a phenomenon which we

still call by his name, phagocytosis, and the recognition of this constituted one of the chief steps in his work on the defensive mechanism. This phagocytosis is really a primitive kind of feeding on the part of the individual cell. If you watch the simplest and most primitive of the protozoa—the creature called Amoeba, which is to be found creeping about in freshwater pools—you can sometimes see it feed. The so-called protoplasm of its body simply flows round and engulfs the smaller creature which it devours. It may be that it is subsisting on these tiny plant cells which we call bacteria. These individually are too minute and too little resistant to be engulfed singly in the ordinary way, but a peculiar waste substance given out by the amoeba's body possesses the remarkable property of causing the bacteria to adhere together into a sticky mass which the amoeba is then able to devour (digested) within the protoplasm of the amoeba: a case of what is called intracellular digestion—digestion taking place within the protoplasm of an individual cell. Metchnikoff's great discovery was that certain of the cells in animals higher in the scale than protozoa retain this ancient power of intracellular digestion, and these phagocytes he found gave the name phagocytes; defence force in the animal body. He introduced little foreign particles into the body of a young starfish and saw how they were devoured and disposed of by the phagocytes; he studied a fungus disease which affected water fleas, and was able to see, as he watched the transparent body of the water-flea through his microscope, how the spores of the fungus which had found an entrance to the body were fallen upon and usually destroyed by the defence force of phagocytes. It would be fascinating to trace out how Metchnikoff proceeded from his basic studies on these lowly organized creatures into the domain of human pathology, but it will perhaps suffice if I say that this great figure in the history of modern medicine, whose foundation work was pure zoology, continued to the end of his days to be a naturalist in his methods and in his outlook.

But it is not merely these great outstanding figures in medicine, when they are tackling its outstanding problems, that show themselves to be naturalists. In the familiar problems of his everyday life the physician finds himself confronted at every turn with problems of natural history, and in grappling with them he uses at every step those methods of observation that are those of the naturalist. He remains, in fact, throughout his working life a naturalist.

THE PHYSICIAN AS TEACHER.

The physician of to-day is, then, like his far back forbear amongst primitive man, a naturalist. The point that I would next make is that in a human community like ours this fact confers upon the physician peculiar power and peculiar responsibility as a teacher. The physicians of to-day constitute the one big section of our citizens who, through their training and their daily work, have acquired a grasp of biological principles. To them, as to no others, falls the task of spreading these principles among their fellow citizens. Human communities are organisms. Here and there, in remote and secluded corners, you may find them lingering in early stages of their evolutionary progress—each little nomad community composed of only a few unspecialized individuals who readily dissolve partnership under the stress of circumstance. While still lingering on here and there in remote spots, where they are free from the pressure of competition, these little primitive communities are on the verge of disappearance. As time goes on they vanish away, often without leaving a trace behind, yielding their place to other communities that have reached a higher grade of evolution.

What, now, are the distinguishing characteristics of these more successful communities? They are precisely the same as those that characterize the more successful, or advanced, human beings usually call them the higher, types of animal organism. The community is composed of an enormously greater number of individuals, and these are not all alike but have undergone specialization for different functions in the community, and finally the individuals are knit together into a highly evolved social organization, so that the able itself to act as an immensely powerful and higher order.

This organization that knits the individuals together and that plays such an important part in rendering the community efficient is

complex and involves many potent though often elusive factors which work beneath the surface of our civilized society: factors which make for the smooth running and efficiency of the social mechanism; factors which have to be appreciated and fostered by the teacher of good citizenship; factors such as self-abnegation—the subordination of the interests of self to those of the community, patriotism, loyalty to comrades, Christianity.

Now the physician, naturalist, in daily touch with living processes, spending his life in the study and treatment of live human beings, knowing so well their frailty and their strength, an optimist, realizing how infinitely commoner is warm-heartedness than cold-bloodedness: who is there that can teach these principles of citizenship with such understanding and sympathy as he? And who, again, is in the position of making his teaching so effective as the physician? Coming into each house on his errand of mercy he necessarily establishes relations of such humaneness and such intimacy as to give his words unparalleled power. In those days of unrest, when the air is filled with the discordant street cries of every kind of fad-monger, do we not greatly need the physician as teacher?

No one who interests himself practically in social problems can fail to realize to what an extent social trouble and friction are due simply to ignorance. The uneducated mind that is blank and yet receptive stands ready to absorb unquestioningly whatever is put before it. But, most unfortunately, the only members of the community that as a rule put anything before it are the extremists. Sometimes these extremists are inspired simply by evil and greed, but far more often—and these are the more dangerous—they are inspired by perfectly honest but lop-sided idealism. They use the simple arts of the demagogue; above all, the classification of their fellow men into sharply demarcated categories. Most usually these are only two in number. They may call them the saved and the damned, or they may use some other pair of adjectives nearly as sweeping; but whatever the pair of adjectives are, they connote respectively agreement and disagreement with the speaker. Those included in the one category are wholly good; those in the other category are wholly evil, and anything in the way of fair and calm judgement is rendered completely impossible.

The physician is eminently qualified to diffuse an atmosphere of sane common sense into the troubled discussion of social problems; his whole work conduces to sanity and common sense. He is accustomed to judge humanity unclothed. He is accustomed to strip off the clothing of humbug and pretence. His interests are with the real man himself, and he has learned that, apart from sex, Nature does not group human beings into absolute categories. He sees his fellow men all fundamentally alike with infinitely varying little differences in detail; he sees through all the same dominating strain of goodness, the same disturbing little elements of evil. Realizing always that men are human he appreciates what a factor in social trouble is the regarding them as so many soulless machines. His constant intercourse with men when they are in trouble makes him kindly and tolerant; at every step he is in touch with phenomena that he cannot comprehend—how much there is even in the simplest living body that no man understands!—and this makes for humanity of spirit.

The physician has, then, in a community like ours, vast powers as a teacher of these principles that mean so much to communal society. He can do much by spreading these principles and also by spreading knowledge of what is really meant by science and the scientific method. He has these powers, and I for one believe that he is constantly, even if unconsciously, exercising them. He may not do ten minutes' formal teaching during his whole life, and yet as he goes about his daily work he is insensibly diffusing around him an appreciation of these principles and these interests. The great majority of our fellow citizens are steeped in the most profound ignorance of what these terms mean, and the result is incalculable loss to the community in all kinds of ways.

THE PHYSICIAN AS BENEFactor.

In ordinary life we are familiar with the benefits we owe to our medical man. He comes in and helps us in emergency. We pay him his fee, and to many a man that ends the matter. He does not feel constrained to be grateful; he feels he has bought the assistance that has been given him; he has paid for the advice and help of his doctor as he might pay for some material commodity or as he might pay for expert help in any skilled operation, such as a bit of

engineering work. But what he is apt to ignore is that in the big things of medicine the monetary payment bears no relation whatever to the value received. If I am at death's door and am saved by an operation the fee that I pay is simply an honorarium graduated according to my means; it in no sense expresses the value of the life that has been given back to me. If I had to assess that value I should probably mention some figure of a totally different order; I might be willing to pledge all my future earnings in return for continued life.

I think we laymen are apt, as individuals, to forget this aspect of medicine—but how much more do we as a community consistently forget it! Just think of the value to the community of the work of a great pioneer in medicine. I will mention two because they happen to appeal to me particularly.

Lister.

Twenty-five years or so ago I had to read a paper of mine to a scientific society. The society was the Royal Society, and in the presidential chair there sat a man who, to my young, impressionable eye conveyed the impression not so much of overpowering greatness as rather of infinite kindness and goodness. There was no oppressive sense of vast knowledge; there was rather the humility of the man conscious of his contact with the infinite unknown. That man had been once a professor in the University of Glasgow. Thirty years before he had been responsible for what is probably the greatest event of world history that has ever happened in Glasgow. He worked in the Royal Infirmary, and there—his big mind able to grasp the practical possibilities that rested on the work of Pasteur—he laid the foundations and erected the main framework of the magnificent edifice of modern aseptic surgery. Most of us here, I dare say, know that grimy old building in which Lister worked—that priceless possession of the Glasgow Medical School, that sacred shrine to which in future ages pilgrims will come from the ends of the civilized earth.

What mankind owes to aseptic surgery can be realized vividly by anyone who cares to read of the horrors of hospital wards in pre-Listerian days. In the hospitals of London, Edinburgh, and Glasgow the death rate of amputation cases averaged about 40 per cent. During the Franco-Prussian war of 1870-71 there were slightly over 13,000 amputations recorded by the French military authorities; of these cases just over 10,000 died. One of the most skilful Prussian surgeons records an unbroken series of thirty-six amputations at the knee-joint, each one resulting in death. In the Munich State Hospital it is recorded that in the year 1874 80 per cent. of all the surgical cases were either killed or badly crippled by hospital gangrene.

However, it is hardly necessary to refer to these old records, for I suppose we may take it that to-day every educated man or woman realizes in a general way what the development of aseptic surgery has meant; most people probably realize that the total destruction of human life in the great war becomes almost insignificant when compared with the total saving of human life which we owe to aseptic surgery. I will therefore not dwell longer on Lister's work: I will pass on and give an example of benefit rendered to mankind from the other side of medical science. I cannot do better than take as my example the case of the mosquito-borne diseases, the successful combating of which we owe above all to Ross.

Ross.

Earlier in the lecture I referred to malaria as being declared by competent authorities to be the most destructive to human life of all known diseases. The malaria death rate in the United States was estimated as late as the year 1908 at about 12,000; the annual economic loss due to it as not less than twenty million pounds.

Now what has been the result of the Ross treatment where it has been applied? In the Panama zone the malarial death rate in 1881 was reckoned at over 2 per cent. of the population; in 1911 it had been reduced by the anti-mosquito campaign to less than 1 per thousand. A particularly interesting case is that of Ismailia. In this town, surrounded by arid desert, there was no malaria until the year 1877, when it was introduced by infected immigrants. In 1900 there were no less than 2,284 cases. Ross himself went out to supervise an anti-mosquito campaign, and the disease was completely eliminated so far as fresh infections were concerned. The general position now is that within any restricted area malaria can be completely controlled. Scattered all over the warmer parts of the world are localities that up to twenty

years ago were deadly to the white man from the prevalence of malaria and in which now the disease has either been completely abolished or reduced to such infrequency as to become practically negligible.

But malaria is not the only one of these mosquito-borne diseases. Yellow fever is another. From time to time this disease used to make its appearance in epidemic form and do dreadful damage. The epidemic of 1821 in Barcelona cost 5 000 lives; that of 1850 in Rio cost 4,160; that of 1853 in New Orleans cost 7,970; that of 1857 in Lisbon cost over 6,000. In Brazil during a period of thirteen years the deaths caused by yellow fever were estimated at 28,078; but in the single year 1899 that country lost 35,557. It was this disease which was the most terrible enemy of the French engineers at Panama; it was impossible to estimate the total number of deaths, but the scale of loss may be imagined from such a simple fact as that "in one ship eighteen young French engineers came over and in a month after their arrival they were all dead except one" (Howard).

Now what was the result of anti-mosquito measures? In New Orleans epidemics occurred in 1853 with 7,970 deaths; in 1858 with 4,854, in 1857 with 3,093, in 1878 with 4,056. Again in July, 1905, an epidemic made its appearance, and by August 12th there were 105 cases. This time, however, anti-mosquito measures were adopted, though no doubt far less efficiently carried out than they would be to-day, and the total number of deaths was kept down to less than 500. In the Panama Canal zone after the Americans had taken it over Gorgas was able to report in 1903 that as a consequence of the anti-mosquito work not a single case of yellow fever had developed during the preceding three years.

I am well aware that to some of my audience to-night these facts that I have been quoting are all well known—they are bits of an old familiar story; why, then, should I take up your time with them? It is because I think they require driving home into the minds of the lay public, not once but again and again and again. If I had my way there would not be a child in this country allowed to emerge from his school days without facts like these being drilled into his ears until they form a permanent part of his mental equipment.

Would it not, indeed, be an immense step forward in our educational methods if we could replace what at present forms so much of the teaching of history in our schools—the more or less legendary tales of the doings of long dead kings and chiefs—by the kind of history that really matters, the history of the intellectual achievement that marks off civilized man from savage? There are no tales more fascinating, more calculated to grip the interest and the imagination, than the stories of how some of the great advances in human knowledge have been made; the stories of how the heroes of science have carried on towards their goal, undeterred by failure and discouragement, it may be in circumstances of great personal discomfort and danger. The advantage that would accrue to science is, of course, obvious: with greater knowledge would come a fuller appreciation on the part of the public of what science really means, and the whole attitude of the community towards science and its encouragement would become entirely changed.

But would there not come also an immense gain to the individual himself? Could he possibly avoid being ennobled and made into a better citizen by being brought into contact with the lives of those who have toiled and fought, not for personal glory or wealth or power, but only for truth and for the good of their fellow men?

However, my purpose just now is not to make out a case for modifying the school curriculum so as to include these chapters of what I regard as *real* history. It is rather to continue to urge the less lofty, but in a commercial age necessary, argument, that the great pioneers in medicine have conveyed to mankind possessions of untold material value. What exactly that material value is can, of course, never be gauged. Our vision is limited. We see only what is close at hand. And our vision lasts only during the instant of our own lives. But still can we not in imagination project our minds back during these last few decades and on into the unbounded future, and become at least dimly aware of these unnumbered invisible hosts whose individual debts are their lives, or at the least their working efficiency? Suppose we had never received the benefaction of aseptic surgery. Suppose we transport ourselves back in imagination to the days of pre-Listerian horror. And suppose that by some supernatural means we became aware of aseptic surgery existing in another planet and of all that it meant—and that it was

available to mankind for purchase after a fair valuation. What would a fair price be—a million pounds, a hundred million, a thousand million? I wonder. Is not any one of these sums obviously ridiculous?

No, the price of each one of these great benefactions of medicine is beyond all the rubies of the world. It is a price that can never be paid, that can never even be fairly assessed. But the benefaction is there: it is ours: and surely it is right that we should occasionally allow our minds to dwell for a little in very reverent gratitude upon the Physician as Benefactor.

I have finished. What I have said this evening hardly merits the title of lecture. It is little more than a group of headings: The Physician as Naturalist; The Physician as Teacher; The Physician as Benefactor. But if you will bear these titles in your memory they may at least serve as pegs upon which to hang future thoughts. And even a clumsily fashioned peg is sometimes sufficient to support a rare and wonderful work.

NINETIETH ANNUAL MEETING

OF THE

British Medical Association.

Held at Glasgow, July, 1922.

E. ROWLAND FOTHERGILL, M.B., B.S., President.

DISCUSSION ON

ALCOHOL AS A BEVERAGE AND ITS RELATION TO CERTAIN SOCIAL PROBLEMS.

(Continued from page 207.)

ALCOHOL AND INDUSTRIAL EFFICIENCY.

BY

EDGAR L. COLLIS, M.D., M.R.C.P.,

Mansel Talbot Professor of Preventive Medicine, Welsh National School of Medicine.

In some introductory passages Professor Collis stated that he accepted the definition of alcohol set forth by the export committee¹ appointed during the war by the Central Control Board (Liquor Traffic)—namely, that alcohol is used to mean ethyl alcohol C_2H_5OH , prepared by the fermenting action of yeast upon sugar. This is the basis of all alcoholic liquors, whether the beverage is consumed immediately after fermentation or at some later period, or whether, as in the case of brandy, whisky, gin, or rum, the spirit is subsequently distilled. Preliminary considerations might be summarized in the statement that alcohol is a substance which can supply the body with a limited amount of easily assimilated energy, but is a narcotic drug or intoxicant capable, if the dose be pushed, of acting as a poison. Alcoholic beverages have a pleasant taste and may be consumed convivially or industrially, but industrial drinking is seldom found dissociated from convivial. When consumed in high concentration the drug effects of alcohol are most pronounced.²

"Industry" is a word generally applied only to physical work connected with some particular form or branch of productive labour, or with some trade or manufacture. Productive labour and manufactures represent man's effort to modify his environment to his needs. Efficiency in industry means the carrying on of this productive labour with a minimum expenditure of energy, whether that energy be physical or mental, or be represented by wages paid to the workers for expending energy or by money expended on raw material or on necessary plant. Industrial efficiency is adversely affected if the return for wages paid is inadequate; if raw material is spoilt during manipulation; or if the plant is not tended so that it works to best advantage.

The subject for discussion, then, is whether the consumption of alcohol exerts any influence, and if so in what direction, upon these matters; we have also to distinguish between convivial and industrial drinking.

EFFECT OF CONVIVIAL DRINKING.

Sullivan has pointed out³ that mortality directly due to alcohol, as measured by deaths ascribed to alcohol and diseases of the liver, places in the same group the agricultural worker (with a comparative mortality figure of 5), who if measured by convictions for intemperance cannot be held to be a great convivial drinker, and the coal-miner (with a comparative figure of 9), who by the same measure is a great convivial drinker (see Table I). For purposes of comparison

TABLE I.—Comparison between Convictions for Drunkenness and Occupational Mortality due to Alcohol.

Town or County.	Convictions for Drunkenness per 10,000 Population in 1911.*	Prevailing Occupation.	Occupational Comparative Mortality 1910-12 for Alcohol and Cirrhosis of Liver.

these occupations may be compared with the clergy, with a comparative mortality figure of 4, or with dock labourers with a figure of 30, and costermongers with a figure of 36, or with inn-servants with a figure of 51, and inn-keepers with a figure of 156. (The figures quoted are for 1910-12.) Estimated by this measure convivial drinking would not appear to exert any marked effect upon health. This measure certainly tends to mask any effect exerted upon industrial efficiency, for few employers of labour would agree that the subject of a drinking bout overnight is as good a workman as usual next day. Nevertheless I am content at this point to leave aside the question of convivial drinking, and rather direct attention to industrial drinking.

EFFECT OF INDUSTRIAL DRINKING.

The habit of industrial drinking, essentially represents chronic alcoholism, but when considering the effect of alcohol upon industrial efficiency the definition of industrial drinking must be widened to include working while the system contains alcohol, whether consumed during or before working hours; for the elimination of alcohol is not immediate, but takes anything up to twenty-four hours to be complete. If this definition be accepted consideration may be given under this heading to the effect of alcohol on physical and mental activities, those activities which determine the return for wages paid, the quality as well as the quantity of output, and the attention paid to plant—in other words, which should determine industrial efficiency.

Bodily activities are of two kinds, reflex acts and volitional acts; frequently the two are combined; but the effect of alcohol may be studied by considering them separately.

REFLEX ACTS.

Two forms of reflex, the knee-jerk and the eye-closing reflex; which have been studied by Dodge and Benedict,¹ may be taken as examples. These observers found that one hour or so after taking a dose of alcohol equal to about 2 oz. of whisky or 1½ pints of beer, the speed of commencement of the knee-jerk was retarded by 9.6 per cent, and the extent of movement was diminished by 48.9 per cent. If the dose was increased the speed reaction and amplitude were impaired still more. The more complex eye-closing reflex was found to be similarly affected as regards speed and extent of movement by similar doses; but in the case of those accustomed to control this reflex voluntarily (one subject was a boxer and another a revolver shot) alcohol weakened the acquired inhibitory control and allowed the reflex to be more active. This capacity for weakening inhibitory control probably accounts for that acceleration of the pulse rate which has been noted to follow a moderate dose of alcohol and has been quoted as evidence of a stimulating effect. In reality this acceleration represents weakening of the cardio-inhibitory tone which normally restrains the heart beat.

Study of the reflexes, then, displays alcohol as a drug which depresses. Direct evidence drawn from industry that interference with the reflex activity impairs efficiency is difficult to adduce. But indirect evidence is to be found in accident occurrence. Certain accidents actually result from or are accentuated by slow reflex action; of these the entrance of a foreign body into the eye or the withdrawal of a hand on feeling pain due to an abrasion, or on contact with hot metal, may be quoted as examples.

Some years ago Dr. Stehr² in Germany obtained figures showing the proportion of industrial accidents occurring on various days of the week. He found that the frequency of accidents on the average for the empire reached its highest point on Monday, and steadily declined until Saturday, which is the usual payday, when it quickly rose almost to the height of Monday. His other data showed with few exceptions that Monday stands at the top of the scale with a corresponding increase at the end of the week. In the milling trade, where Monday and Saturday changed places, payday usually falls on Friday. In Lower Alsace, where Friday stands next to Monday in number of accidents, there are many trades in which Thursday is payday. The distribution of convictions for assault in the empire which are generally ascribed to alcohol, show a weekly distribution agreeing with that for accidents; and convictions for drunkenness in Hildesheim, a city possessing most careful records, follow the same course. Dr. Stehr, after carefully weighing up

TABLE II.

Period.	Statistical Group.	Monday.	Tuesday.	Wednesday.	Thursday.	Friday.	Saturday.
Proportion of accidents occurring on different days:							
1897 ...	German Empire...	17.6	16.7	15.7	15.7	15.1	17.0
1885-1893 ...	North Austrian building trades	18.7	15.6	15.5	16.2	16.6	16.2
1889-1899 ...	General milling ...	16.7	15.9	14.9	14.6	15.9	17.3
1838-1893 ...	Land and forest cultivations..	16.8	15.9	16.0	14.7	15.6	15.5
1837 (40 weeks) ...	Shipbuilding concern, Hamburg	19.2	16.9	16.3	14.9	15.2	17.5
1838 ...	Lower Alsace ...	11.0	← Excess over weekly average →				10.0
Average convictions for assaults:							
1818-1899 ...	German Empire...	125	69	62	1	4	103
Convictions for drunkenness:							
1836-1902 ...	City of Hildesheim ...	224	148	99	86	119	144

facts here quoted, as well as other evidence, concludes that the variations in accident frequency may safely be attributed to the use of alcohol, even though that use is not immoderate.

Dr. H. M. Vernon has investigated accident occurrence from this point of view,⁵ taking advantage of the liquor restrictions during the war. He studied the occurrence of accidents during the first, second, and third shifts of night work. Before any restrictions existed there was the usual opportunity for drinking before starting work; at that time there were among men nearly twice as many accidents in the first spell of work as in the last, and among women 1.6 times as many. Under restrictions this proportion fell to 1.4 for both sexes (see Table III).

TABLE III.—Ratio of Accidents in Three Spells of Night Work.

Alcohol Consumption.	Period.	Men.			Women.		
		1st spell	2nd spell	3rd spell	1st spell	2nd spell	3rd spell
Rather less than pre-war.	February—July, 1916	1.9	1.0	1.2	1.6	1.2	1.0
74 per cent. of pre-war.	August, 1916—March, 1917	1.5	1.5	1.0	1.4	1.3	1.0
29 to 39 per cent. of pre-war.	April—October, 1917	1.4	1.0	1.0	1.4	1.2	1.0

Vernon also noted that before restrictions in 1915 there were far more accidents on Saturdays and on Mondays than on other days in the week; wages were paid on Friday afternoon. But during 1916–17 the number of accidents was nearly the same on each day of the week; during this latter period shorter hours provided opportunity for spending money on drink on any day of the week, and at the same time restrictions were limiting the amount of alcohol available. This evidence receives confirmation from America, where the National Steel Construction Company report⁶ that whereas previous to the Prohibition Act, which came into force in July, 1919, 75 per cent. of accidents occurred on Monday and Tuesday, now the percentage of accidents is no higher at the beginning of the week than at the end.

The evidence thus far refers to the effect of alcohol upon the distribution of accidents; the inference being that the unequal distributions noted are due to the influence of alcohol in scolding up the accidents at certain periods. The real test of course is the absolute prevalence of accidents occurring. Here some useful data are available⁷ from the Department of Labour and Industry, Harrisburg, which show the number of fatal accidents in the last six months of each year for 1916, 1917, 1918, and 1919, only the last period falling within the provision of the Prohibition Act. The fall in that period, following upon a steady rise in the previous years, is marked; further, it occurred during a period of unusually good trade.

Industrial Accidents (Fatal).

Last six months, 1916	1,454
Last six months, 1917	1,537
Last six months, 1918	1,647
Last six months, 1919	1,233

Further definite evidence comes⁸ from the United Pocatontas Coal Company, who state that:

"Our mines are in West Va., and we have had Prohibition there for about five years. We have had better service from the men than ever before; and, better than anything else, the accidents have been only about one-third as many. And when you think that the deaths by accident are but one out of three of what we had before we had Prohibition, it seems to me that anyone that loves his fellow man will favour the cause of Prohibition."

The President of the Gulf States Steel Company⁹ has written that accidents in the plants of that company have been reduced since prohibition went into effect by at least 75 per cent.

- Deduction.—The depressing effect of alcohol upon reflex acts is detrimental to efficiency if industrial accidents are used as a measure.

VOLITIONAL ACTS.

The efficiency of a willed act may be estimated in several ways: (1) by the power of the muscular effort; (2) by the ability of the subject to continue the effort—that is, to resist fatigue; or (3) by the accuracy of the effort having regard to its purpose. No definite evidence has been acquired under industrial conditions of the effect of alcohol upon the efficiency of willed acts as measured by either of these methods of estimation. Indeed, the requisite conditions for obtaining such industrial evidence are practically impossible to find or establish.

Experimental Evidence.

Evidence bearing on the subject is, however, forthcoming from laboratory research. The investigations of Rivers¹⁰ are probably known to all: they were aimed at testing the effect

of alcohol upon muscular contraction—namely, pure muscular fatigue. He used the ergograph and employed cleverly contrived control experiments; his results agree with those of earlier observers in failing to demonstrate that moderate doses of alcohol exert any appreciable influence upon simple muscular contraction. They also agree well with the indication to be drawn from Mellanby's later work that alcohol is not a source of energy for muscular contraction. This point is important since, if the combustion of alcohol only supplies heat to the body and not energy for the contraction of muscles, any claim is removed that alcohol is of use to the industrial worker, on account of its value as a partial food. Mellanby further found evidence that if the concentration of alcohol in the body is high the oxidation of other sources of energy is thereby limited when intermediate oxidation products accumulate and as a consequence expedite the onset of fatigue. He also noted that alcohol passes into the blood more rapidly if taken on an empty stomach, and that food, and especially cream, if consumed at the same time delays absorption.

The influence of alcohol upon the nervous tissues may be tested through neuro-muscular co-ordination. This aspect has received attention from Vernon and others.¹⁰ They found that a quite moderate dose, such as a glass of wine or a pint of beer, was invariably followed by a reaction in the direction of diminished control of the muscles. No initial improvement, even of brief duration, was experienced; and the reaction was about twice as great if the dose was taken on an empty stomach. They conclude that

"in all work with the hands requiring skill and delicacy of muscular control one may be confident that, whilst strictly moderate quantities of alcoholic liquors taken by persons accustomed to alcohol may not appreciably reduce manual skill, they can seldom, if ever, improve it. Moreover, such persons continually run the risk of finding their manual skill quite appreciably reduced if they happen to take their alcohol on an empty stomach instead of a full one. It would be far better for them to avoid the risk altogether by postponing their consumption of alcohol till the day's work is over."

Particular interest attaches to another inquiry, carried out by McDougall and Smith,¹¹ who, after investigating the action of various drugs, group alcohol with chloroform, and consider that both act chiefly and immediately by raising the resistance of the synapses in all parts of the brain, so impeding nerve impulses. True stimulants such as strychnine and tea produce opposite effects. These observers also noted a new point—namely, that although alcohol acts deleteriously during the stages of increasing inefficiency caused by protracted fatigue, yet it acts beneficially as the subject begins later to regain his previous efficiency. This instance, which is the only one of alcohol improving efficiency, may have its importance in relation to recovery from overfatigue in industry; but since overfatigue should be avoided the value of alcohol with respect to it ought not to be needed.

Throughout the experimental work referred to one point is frequently noted—namely, that the subjects when reacting to alcohol were generally under the impression that the test was being performed unusually quickly and accurately, and could with difficulty be convinced to the contrary even when faced with the results. This point in itself indicates the narcotic influence of alcohol upon powers of judgement and discrimination.

These observations prepare the way for considering evidence gathered from industrial experience of the effect of alcohol upon efficiency.

Industrial Evidence.

Evidence from industrial experience is difficult to establish on a scientific basis. Experience during the war, when liquor restrictions were in force, might have afforded useful records had not other influences, such as long hours and pressure of work, also been at work simultaneously.

Appeal is often made to records of lost time, and the opinion has been expressed that this interference with industrial efficiency is markedly influenced by alcoholism. There can be little doubt that there is reason for this opinion. Lost time varies greatly in different industries; it tends, for instance, to be high in coal-mining, ship-building, metal-smelting, and dock labour, and these are all industries in which convivial drinking is high. Yet the evidence is not clear; for in these industries, owing to the need for physical fitness, a worker may wisely stay at home on account of some minor disability, such as a slight sprain or rheumatism, which, if he were a tailor or printer, he would disregard. Again, fatigue engendered by hard physical work or adverse conditions of employment may be a direct cause of turning, to

alcohol; and so industry may tend to increase that alcoholic habit which, in its turn, acts detrimentally upon lost time. Apart from factory conditions and the amount of physical energy demanded, lost time is particularly influenced by the distribution of working hours; and Loveday has shown¹² that in comparatively light engineering work, when work is started before breakfast, the amount lost—10 to 20 per cent. of possible hours—may be as high as that which prevails in coal-mining, while if before-breakfast hours are not worked lost time is three or four times less in amount. Factory cannot, then, be compared with factory, or industry with industry, with regard to the alcoholic habits of the workers and the amount of time lost, unless information is available as to hours of work, the nature of the work, and the conditions of employment. Hence the difficulty of estimating accurately the effect of alcohol upon lost time.

Nevertheless Loveday, when investigating time lost before breakfast, found that Monday is universally the worst day. Stehr, whose work has already been quoted,¹ has pointed out that absenteeism resembles the occurrence of accidents in not being distributed evenly throughout the week. He gives the following figures for a colliery in Moravian Austria:

Days.	Percentage of Absentees.	
	1898.	1893.
Usual week-days	5.0	6.9
Days following Sundays and holidays ...	7.5	9.3
Days following advance pay-days	8.9	10.4
Days following regular pay-days	10.4	12.9

Although more recent investigations into industrial fatigue may call for some modification of the interpretation Stehr places upon the data quoted and other evidence he obtained, he does establish that a day of recreation is frequently more "fatiguing" than a day of work, and that this phenomenon is most pronounced among habitual drinkers. In view of other evidence he is probably justified in attributing much of the loss of efficiency so indicated to the use of alcoholic beverages.

The best evidence is probably that forthcoming under prohibition from America, where the only variant has been the opportunity for obtaining intoxicating drink.

Thus the Chesapeake Marine Railway Company report⁶ that: "Prior to Prohibition we always had what was known as Blue Monday in shipyards; there being so many workmen absent that it was a hard matter to carry on the work of the yard with any degree of efficiency. With Prohibition in force, we can accomplish as much on Monday as any other day."

The Kittanning Iron and Steel Manufacturing Company⁶ say: "In our puddle mill department, for the first time or so after each day, we seldom had more than 25 per cent. of our furnaces in operation; the number on each turn increasing towards the end of the week. Since Prohibition went into effect, we have found that between 90 and 100 per cent. of our men work practically full time, the only losses being due to possibly sickness or some element beyond the control of the men."

The Spang, Chaffant and Company,⁶ who represent yet a different industry, declare that: "Monday mornings and Monday nights in the mill were periods of great difficulty and anxiety, because the week-end drinkers would be absent from their posts of duty in such numbers as to make the operation of the mill almost impossible, and difficult at best. After the saloon was abolished this trouble disappeared."

A mining engineer at Iron River reports⁶ that: "At our mines for the first nine months after the State of Michigan went dry the number of days of absence from work due to accidents fell off 68 per cent. This seemed so startling to me that I made an inquiry in a large organization near by and their results were practically the same."

These statements might be multiplied without materially strengthening the proposition that alcohol consumption conduces to lost time and so interferes with industrial efficiency. Before, however, leaving this point regard should be paid to the prevailing custom of paying wages at the week-end, just when the worker is tired and has free time ahead for indulging in alcoholic recreation. Probably lost time on Mondays would be greatly reduced by paying wages on Monday evening, a scheme put forward by Vernon as advantageous from other points of view.

Another great cause of lost efficiency is *labour turnover*. The financial loss so caused was crudely estimated¹³ at the meeting last year at Newcastle. No evidence is forthcoming from this country as to how labour turnover is influenced by alcoholism; nor, indeed, is it directly obvious that such an influence must exist. Nevertheless the Appleton Company, Lowell, Mass., consider⁷ that since prohibition their labour-

turnover has been reduced. So few industrial concerns ever consider the importance of labour turnover or calculate its amount that this statement has significance. As a set-off, however, the findings at Grand Rapids¹⁴ must be quoted that the change has made for restlessness, especially among the younger workers, and in some cases it has slackened effort and swelled the labour turnover.

Lost time and labour turnover are, after all, only indirect methods of measuring industrial efficiency. The true test must be *work done*. Here, for lack of other evidence, we must turn again to America. A few statements made by firms representing different industries bear on the point.

J. Edward Horn and Company state⁶ that: "When our war-time Prohibition went into effect, July 1st, 1919, we immediately saw big changes in the production of bituminous coal by our miners. As time passed we realized that each miner was producing more coal per day and worked far more regularly than he did when he was able to get strong drink."

The Potts Run Coal Company remark⁶ that the efficiency of men has increased about 25 per cent.

The Ashland Steel Company have written⁶: "We beg to advise that we operate a Bessemer steel plant and wire rod mill. Since Prohibition has been effective in this country our scrap loss in our rod mill department has been reduced 25 per cent., and we have a better character of workmen than ever before."

The American Locomotive Company hold⁶ that prohibition has caused considerable efficiency in all departments. The Sun Shipbuilding Company maintain⁶ that their men "are worth 20 to 50 per cent. more to their company on account of their ability to give better services."

Alcoholism and Food.

Alcoholism affects industrial efficiency indirectly through yet another channel. The energy needed for industrial activity is obtained from food; but where the alcoholic habit prevails appetite is interfered with and wages are spent on drink which should be spent on food. Interest attaches to expenditure in the United Kingdom on food and on alcohol. The comparative figures for 1919 were as follows:¹⁵

Food.			Per head.	
			£	s. d.
Beef and mutton	4	4 8
Bread and flour	3	11 8
Milk	2	14 4
Bacon	2	3 5
Butter and margarine	1	17 0
Sugar	1	1 8
Total	15	12 9
Drink.			£ s. d.	
Alcoholic drink	8	8 0
Tea	0	19 7

Certain foods, such as fruits, vegetables, eggs, cheese, and potatoes, are not included in the expenditure stated; probably they may fairly be included at something over £1—say, for convenience, £1 3s. 3d. Then the comparative expenditure on food would be £16 16s., or only twice as much as is spent on the harmful luxury alcohol. These figures are referred to because the proportion of income spent on alcohol is greater as the social status of the spender is lower; in other words, manual labourers who expend energy and need more food to supply it, spend proportionately more on alcohol than do non-manual workers; and efficiency suffers.

CONCLUSION.

Alcohol possesses a charm for removing the irritating effects of industrial fatigue, but it is a charm purchased at great cost to efficiency. The evidence drawn from American sources as to the beneficial effect upon industrial efficiency of prohibition when taken as a whole can hardly be controverted, even though it may be criticized piecemeal.

Throughout the United States prohibition was established on July 1st, 1919, but some of the States went dry before then—for example, Kansas thirty-five years before, North Carolina in 1908—and the movement was spreading. Over here before the war the competition of America was being keenly felt, and the question was often asked how it was that in the States, although higher wages were paid, yet goods could be produced cheaper. Clearly their industrial efficiency was higher. If this greater efficiency depended in any way upon partial prohibition, it may become far greater under total prohibition. This country depends upon her industrial efficiency. All evidence points to this efficiency being materially affected by alcoholic habits. The time is not far distant, if it is not now with us, when, in the interests of efficiency, we may be compelled, if those habits are not rapidly brought within temperate limits, to follow the example of America.

SUMMARY.

- Alcohol is a drug possessing energy which the body can, but probably not for muscular work.
- Alcohol interferes adversely with reflex acts and neuro-secular co-ordination. The higher the concentration in which it is consumed the more pronounced is the effect.
- Alcoholic habits vary with industries, and where most pronounced time-keeping is most irregular.
- Industrial accidents are increased by the consumption of alcohol even though in moderate amounts.
- There is no evidence, either experimental or practical, that alcohol is advantageous to industrial efficiency, and that it is harmful.
- Prohibition in America appears to be associated with a fairly improved industrial efficiency, whether measured by accident frequency, lost time, or output.

ALCOHOL RESTRICTION AND MORTALITY.

BY
DR. M. HINDHEDE,
Copenhagen.

WHEN the total blockade came into effect in February, 1917, very critical position developed in Denmark, as will be seen in the following figures:

Average Yearly Crop (Millions of Kilograms per Million Inhabitants).

	Germany, 1912-13.	Denmark, 1913-16.	Denmark, 1917.
Oats	175	105	76
Wheat	66	68	40
Bread grains	241	173	116
Rye	54	204	132
Potatoes	767	349	294

As we in Denmark before the war used to import nearly as much a quantity of grains as our own crop, and as our crop in 1917 on account of the drought was greatly reduced, one can easily see that the situation was very critical—indeed, a catastrophe was really pending. The situation seemed the more critical as we knew that the Germans were starving, in spite of the fact that Germany under ordinary circumstances used 50 per cent. more of bread grains and over twice as many potatoes in proportion to its population.

It was a great satisfaction to me to be called upon to act as member of the committee appointed to deal with the question together with Professor Holger Møllgaard and to share with him the responsibility for the physiological side of the question. Here we really would have a very rare opportunity for an exceptional experiment with three millions of people. Nothing could be easier than to procure sufficient nourishment, if only the newer principles of nutrition were followed and the bill of fare made up principally of milk and vegetables. We recommended especially potatoes and barley porridge. Extensive experiments carried out in the laboratory of which I am the head have proved that young and strong men may live year in and

year out exclusively on potatoes and barley porridge, sugar, and perfect health and vigour.

It is further proved through our experiments that a person may live for two years or longer in excellent health and good working capacity without fat if he only gets sufficient fruit and green vegetables, which contain the same vitamins as are found in butter. Further, we have proved that man can digest the bran of wheat and rye to the same extent as it is digested by the domestic animals. This seems to disagree with older experiments, but these were presumably not carried out in the right way—the mistakes can easily be demonstrated. Our experiments with bran have been repeated by Professor Johansson of Stockholm and Professor Wiegand of Zürich with quite similar results. Bran is, after all, one of our very best foods. Persons that I have employed in experiments have lived half a year on whole wheat bread (or rye bread) and margarine only. When the same persons tried to live upon white bread and margarine alone they became so weak after three weeks that they could hardly walk.

The said committee calculated that to produce pork and bacon by the help of barley and potatoes meant a loss of nourishment of 80 per cent., and such an extravagance would under the circumstances be perfectly unjustifiable. We also found it perfectly unjustifiable to use the same good foods for the production of alcoholic drinks. Space will not permit me to go into details; I will only mention that the unanimous propositions of the committee were adopted by the Danish Government and Parliament. Professor Møllgaard had the main responsibility as far as the practical administration was concerned, and the speaker was given the task of writing a pamphlet of direction for housewives. This pamphlet was printed in an edition of 40,000 copies and sent out by the Government. The ration system was in its essentials carried through in Denmark without any particular opposition. People entertained no anxiety as to being undernourished.

Our chief measures were:

1. All bread cereals and most of the barley and potatoes were requisitioned by the Government to be used as food alone for the people.
2. As a result of this measure the raising of pigs was reduced to one-fifth. The small amount of pork which was available was eaten by the farmers. The city folk got hardly any pork.
3. The rye was ground out to 100 per cent., and thus rye bread contained all the bran. In addition to this, 12 to 15 per cent. bran of wheat was mixed into the baking of rye bread—that is to say, all the bran which was left over in making white bread was made use of in this way. Because of this the domestic animals had no bran in their feeds while the ration system was in force.
4. All production of alcoholic liquors for general consumption was prohibited. All supplies on hand were seized, and of the supply only 100,000 bottles (each containing 750 c.cm.) were given out every month, which meant 25 c.cm. of alcoholic drink for each person a month. In order to avoid any special fight for this dram, there was placed so high a tax on spirits that the price went up to an amount twenty times higher than was normally paid.
5. The production of brewing of beer was reduced to one-half the ordinary output, and the amount of alcohol contained therein was not allowed to exceed 3 per cent.
6. In addition to these regulations all export of fruit and vegetables was prohibited.

Through these measures we easily succeeded in making sufficient food available, and none needed to starve. In fact, we had a surplus of bread grains, so that we were able to render assistance to our needy neighbouring nations. But our bread-porridge-potato bill of fare did not appeal to the palate of our people as did the old meat diet, and as a result a reduction in weight of from 2½ to 5 kilograms was quite common.

The question which now presented itself was, What effect would this diet, which contained such small amounts of albumin, fats, and alcohol, have on the general state of health? We have made this matter a subject of a thorough-going statistical investigation, and we have made use of the mortality ratio as a standard.

his respect is that the water in which the porridge is taken (as a soup) with the potatoes, especially

lenigsmønstret om Rationeringens
[The influence of the rationing on
the interior.] Short résumé in
[Lund.] This work has been critically
reviewed by Professor Harald Westergaard, who

...h people, and I d-
...been carried thr-
...basis, and that the conclusions drawn by the
...the observations at hand. It seems to me desirable that the main results
...should appear in a language universally understood." The investigation
...reaches to the end of the year 1918. The figures are here made available
to the end of 1921.

The Effect of Alcoholism upon Mortality.
This will clearly be seen from the following figures:

Yearly Consumption of Alcohol per Head in Lites (Denmark).

	1900-09.	1910-14.	1915-16.	1917.	1918.	1919.	1920.	1921.
Spirits (50 per cent.) ...	11.3	9.2	8.5	2.6	0.4	1.0	1.5	1.1
Pure alcohol in spirits, beer, and wine	7.8	6.6	6.2	3.2	1.5	2.3	2.8	2.5
*Cases per year in Copenhagen of—								
Delirium (reported) ...	760	565	390	124	14	11	17	20
Deaths from alcoholism	100	82	50	18	2	5	14	17

* Calculated per 500,000 inhabitants.

According to the old physiological view the theory was taught that a diet poor in albumin lowered the power of resistance against disease. While there was a drop in the death rate from alcoholism it was therefore difficult to know beforehand whether the total mortality would rise or drop. If the new theories were reliable then one might expect to find a falling off also in the total mortality. Unfortunately, however, the investigation was interrupted by the influenza epidemic which began to show itself in July of 1918, but did not get hold seriously till the last quarter of the year, but continued, with abating force, through 1919 and 1920. We have endeavoured to eliminate this interruption in two ways: (1) I have compared the death rate after the deduction of the figures for epidemic diseases; (2) I have made a special calculation for the year from October 1st, 1917, to October 1st, 1918. This year is the most typical of the years under the rationing system, as the most stringent measures were put in force on October 1st, 1917, and continued through 1918, until they gradually went out of effect in 1919. Alcohol restriction was already put in force in March, 1917. During the year of the rationing system only 100,000 bottles of spirits were given out each month, but in the fourth quarter of 1918 the allowance was raised to 300,000 bottles (the people had to have their Christmas spirits!), and this allowance has since been followed (see the figures below, also Diagram II).

Average Yearly Deaths per 100,000 in Copenhagen, Ages 25 to 65 Years.

	1920-09.	1910-14.	1915-16.	1917.	Oct., '17-Oct., '18.	1918.	1919.	1920.	1921.

Ratio (1910-14 = 100)	94	100	103	97	83	88	93	92	92

Taking as our starting point the last five years before the war (1910-14), when the death rate was lower than ever before, we find, when we only take the male population into account and exclude epidemic diseases (B), from October, 1917, to October, 1918, a drop of 398 deaths, or 30 per cent. (C). A little increase is observed in 1919 and 1920, but in 1921 when the influenza epidemic is gone we find the death rate is still a little lower. The last drop, however, is due to

the decrease in other diseases of infection, tuberculosis and pneumonia (D). Whether this drop has anything to do with the ration system cannot be stated with absolute certainty. The mortality has been on the decrease in the case of these diseases during the last generation. During 1890-99 the figures were 496, while, as will be seen, they had dropped 171 in 1910-14. The increase which was observed during the first years of the war can easily be explained because of the poor housing conditions and the scarcity of fuel. People had to crowd together in small rooms. While the same difficulties continued in 1918 we see a considerable drop in the death rate. From this we are justified in arriving at the conclusion that the diet, consisting mostly of vegetables, does not seem to have lowered the power of resistance against tuberculosis.

Because of many other factors which have to be reckoned with in this conjunction, we believe it to be correct, in order to make the effects of the rationing system clear, to subtract the last figures—that is, not to take the infectious diseases into account. By doing this we arrive at the figures as stated under E, which in the case of men from 1900-16 seem to be about constant until the rationing system was put into effect, when they drop 34 per cent., followed by a rise in 1921, of 8 per cent. In the case of women we can trace a rise during the first sixteen years of the century, but during the time of the rationing system we observe a drop of 17 per cent., followed by a now rise till 1921.

It will be noticed that the drop in the case of men is extraordinary. It cannot be an accidental year variation. When we take the figures for each year from 1900-16 we find that the figures in regard to "all other diseases," E, vary but 7 to 8 per cent. over or below the average. 34 per cent. is altogether too far outside the border of variation. There must be a reason for this, but what? There may be several reasons, but everything indicates that the main cause can be found in alcohol restriction.

1. The drop and the rise harmonize in the main with the decrease and increase in the consumption of alcohol. The objection can be made that in proportion to the drop in the use of alcohol the death rate from 1900-16, as far as men are concerned, ought to have been larger. In the case of women we find that there has been a noticeable rise. This fact, however, is not conflicting with the drop in the consumption of alcohol. The use of alcohol among women has, without doubt, been increasing, while it has been on the decrease

DIAGRAM I.

among men. It is evident that especially among the so-called better or upper class of society it has become fashionable for the women to take spirits. It is very noticeable, too, that tobacco smoking is rapidly increasing among the fair sex.

The increase and decrease in the use of tobacco and coffee will be seen from the official figures which cover the import of these articles. (See diagram II.) It should be observed that import and consumption do not always cover each other,

because of the fact that great supplies of tobacco were obtained and large quantities of tobacco were raised in Denmark during the war. Tobacco could for this reason always be had, while we had to be content with substitutes for coffee.

DIAGRAM II.

Denmark ranks normally next to Holland as the heaviest users of coffee in Europe, while the Englishman drinks an incredible amount of tea. The consumption per head in kilograms in 1913 was:

	Holland.	Denmark.	Belgium.	France.	Germany.	England.
Coffee ...	8.60	5.50	5.14	2.90	2.44	0.27
Tea ...	0.88	0.10	0.03	0.03	0.06	2.99
	9.48	5.90	5.17	2.93	2.50	3.26
Tobacco ...	3.56	2.20	2.61	1.11	1.50	0.94

2. The difference between the death rate among men and women was reduced to a minimum. Before the war the death rate of men in Copenhagen, in the ages from 25 to 55 years, was 50 to 60 per cent. higher than that among women. In a statistical work which I already had published before the war and made for the Sobriety Commission, I had, in conformity with others who have been doing research work on the alcohol question, arrived at the result that the difference in the main was probably due to the consumption of alcohol by the men, and not to the difference of occupation. For this reason I was naturally very eager to get hold of the results of the rationing system and to ascertain whether they would prove my point. They did so, as will be seen from the following:

	1910-14.			October, 1917-18.		
	A.	C.	E.	A.	C.	E.
Men ...	1363	1333	1008	985	935	666
Women ...	886	855	671	760	720	559
Difference ...	483	477	337	225	215	107

The difference, as will be observed, amounts either to one-half or one-third. In fact, if the death rate among the women had not fallen off, the difference would practically have disappeared.

	A.	C.	E.
Men, October, 1917-18 ...	935	935	666
Women, 1910-14 ...	886	855	671
Difference ...	99	79	+ 5

It is probable (compare the experiences of the English life insurance companies) that if the rationing system had been continued in the same manner the men would have overtaken the women—in fact, the possibilities are that the figures would have gone below the figures shown for women. This would mean that the death rate among men would have been reduced to one-half its former size. What this would mean for families, as well as for society in general, needs no further explanation.

But the most surprising is, in my opinion, not the reduction in the rate but the rapidity of the reduction. The most natural explanation of this seems to be that the effects of alcohol are not limited to drunkards only. It must be evident that the main effect lies in a lowered power of resistance also through a moderate consumption of alcohol, and therefore those who drink alcohol in moderate quantities die like flies when disease sets in. But the question might be raised, Is alcohol restriction the only cause of this remarkable reduction? I hold that the change of diet also plays an important part, and my supposition is based especially on observations made with reference to the death rate during the latter years of life.

Death Rate in Copenhagen at Ages 65 to 100.—Average Yearly Deaths per 100,000.

	1900-09.	1910-14.	1915-16.	1917.	Oct., '17-Oct., '18.	1918.	1919.	1920.	1921.

Under the heading of infectious diseases are gathered all deaths from epidemic diseases, tuberculosis, and pneumonia. These diseases play a comparatively small part in old age. We find practically no deaths here from influenza. When we consider, as stated before, Group E, we find in 1918 a reduction of 21 to 22 per cent. in the case of men, and 10 per cent. in the case of women. The death rates of men and women come closer together. This may, of course, be due to alcohol restriction. But there is something else which does not harmonize—namely, the rise in 1920-21, and especially the rise in the case of old women. We cannot suppose that they consume very large quantities of spirits. In order that this problem might be solved, I have investigated the death causes which particularly might be the cause for this increase during the last two years. The answer is: *Heart diseases, bronchitis, bronchopneumonia, and senility*—that is to say, the real old-age death causes.

We notice how these old-age ailments invariably and regularly decrease both in the case of men and women during the time of rationing, while they return to normal as soon as the rationing system is abolished. Practically speaking, we find no difference between deaths of men and women in these diseases. From this we gather that there must be some cause for this invariable drop and rise, but it cannot be that alcohol is the guilty one. But where is the cause to be found then? I make my guess, On the Spartan, spare diet, together with the scarcity of coffee. I have no doubt but that it is advisable and wise, especially for old folks, who as a rule live

a comparatively quiet life, to eat but little, and it is not at all improbable that a lacto-vegetarian diet here is greatly to be preferred.

*Three Main Causes of Death in Old Age in Copenhagen.
(Deaths per 10,000.)*

	1920-22.	1910-14.	1915-16.	1917.	Oct., '17- Oct., '18.	1918.	1919.	1920.	1921.

Women ...	95	100	111	113	75	81	94	111	111

We can dispute the explanations, but the fact remains nevertheless that in Copenhagen, a city of about half a million inhabitants, 1,100 people over 25 years of age were saved during the time of the rationing system when we compare the figures with 1910-14. For the entire country, with a population of three millions, the saving of life for all ages amounted to 7,500, or if we reckon in proportion to the year 1913, the year the death rate was at its lowest, the figure stands at 6,300. In other words, the death rate for the entire country dropped from 12.5 to 10.4 per thousand, which is the lowest mortality figure that has been registered in any European country at any time. This is, therefore, probably the greatest hygienic advance ever made in so short a time. All hygienic measures are as a rule expensive, but the rationing system not only did not cost anything, but through our inexpensive diet and economy in regard to the use of alcohol the country saved hundreds of millions of kronen.

We have spoken only of the death rate, and have not touched upon the moral advantages which alcohol restriction has carried in its train. But anyone who will look at the figures presented can judge this for himself. It must be remembered that Denmark, as far as the mortality rate is concerned, already was one of the most favorably situated countries in Europe, and this notwithstanding the fact that 40 per cent. of her population was located in the cities. What it would mean to the larger nations, if through a similar mode of living they reduced their death rate to 10.4 per thousand, is self-evident.

Country.	Consumption.		Inhabitants (millions).	In Cities per cent.	Mortality rate per 1000 (1913).	No. saved if Mor- tality is 10.4.
	Alcohol (100%) (Litres).	Spirits (Litres).				
France ...	22.4	7.9	40	41.3	17.7	292,000
Great Britain and Ireland	9.3	3.5	47	63.2	14.3	183,000
Germany ...	6.7	5.8	63	47.2	15.0	313,000
Denmark ...	6.0	9.2	3	40.2	12.5	6,300
Sweden ...	4.2	6.7	5.7	27.2	13.7	18,800
Norway ...	2.7	3.4	2.5	28.5	13.2	6,500

Why should it not be possible in beautiful France, where the ratio of city and country dwellers is similar to that of Denmark, to bring the mortality rate down to a level with that of Denmark, such as was demonstrated during the rationing system there? If it were carried through, 300,000 lives would be saved annually—that is to say, the growth of the population would increase from 1 to 8 per thousand, and the critical question of repopulation in France would be solved.

C

The weak point in the Danish experiment lies in the fact that we not only restricted our alcohol consumption but we changed our entire mode of living. I would recommend to the British people that they should stop all production and consumption of alcohol for the next two years and continue to live as heretofore. If no essential difference is found with reference to the mortality rate at the end of this period, then I would say, keep on quietly and unconcernedly with your drinking. But should it be proven, against expectations, that 50,000 to 100,000 lives were spared, then I suppose that no intelligent and sensible man would wish to re-establish full liberty in a poison so dangerous. This is, at any rate, the situation in Denmark. There are hardly any, except the distillers and brewers, who desire to return to the old conditions, and the fight will be between prohibition and a strong rationing system.

DISCUSSION.

Sir THOMAS OLIVER (Newcastle-upon-Tyne) said that there was little doubt that within the last fifty years all classes of society in this country had been marching towards sobriety. He compared life in the army four decades ago with the conditions prevailing to-day. The men were better paid, the discipline was more humane, the recruits were drawn, if anything, from a better class of society, or at any rate were better educated; also they were worked harder and had not so much time on their hands as their predecessors. He questioned whether the modern recruit could go through the hard training required of him if he consumed beer to the extent which was customary in former days. The same was true of the navy. Thirty years ago it was the common custom for many of the seamen who had been given leave of absence to return to their ship in a condition of physical unfitness from drunkenness; this was no longer so. A similar improvement was observable in the merchant service, although there were still many defaulter. In the field of industry absenteeism on Mondays was still one of the discomposing circumstances which employers had to face, and no doubt free indulgence in alcohol over the week-end was responsible. The amount of drink consumed was influenced to some extent by the state of the labour market. When casual labour was scarce the men who found employment received larger wages and were apt to spend more on drink. While high wages tended to social and moral betterment there were exceptions, in which high wages, especially for youths, laid the foundation of drinking habits. No wages at all, however, might be equally harmful, and week after week men who were receiving the dole were brought before the bench for drunkenness. A great responsibility rested upon foremen and heads of departments in the factories, since by their example the habits of the younger men were influenced. There were certain occupations in which the workpeople drank more than in others—occupations which had to be carried on in high temperatures or in humid atmospheres, causing perspiration, or in dusty trades, causing dryness of the throat. Each industry should tackle the question for itself. Many works canteens, offering cheap, wholesome food without stimulants, had gone far to solve the problem. More facts were needed, slowly accumulated and carefully tested, as to the extent of unfitness for work which alcohol produced in those who consumed it freely. The speaker quoted some figures which showed that in a coal-mine in South Wales the total miners sent to bank 100 tons of coal for every 72 sent up by miners who indulged too freely in alcohol; also that in an electrical engineering works in the South of England, where all the employees were abstainers, the absenteeism only averaged 0.5 per cent., and the accident claims 8 per cent. of the premiums paid, whereas in workshops generally accident claims formed 65 per cent. of the premiums paid. Sir George B. Hunter, of the shipbuilding firm of Swan, Hunter, and Richardson, had given him the comparative number of hours worked by riveters who were abstainers and riveters who were known to be unsteady. The investigation extended over three weeks and included overtime. The average number of hours worked per week by six total abstainers was 67, 62, 61, 70, 70, and 55; and by four men who were known to be unsteady, 45, 51, 43, and 29. The number of hours worked overtime by the first six was 14, 11, 6, 16, 17, and 6, and by latter four, 16, 10, 3, and 3. Aschaffenburg showed that alcohol lessened the amount of work done; his experiments with the ergograph showed that before the alcohol which had been consumed had had time to lessen the amount of work done there was usually a primary but short-lived increase, as indicated by a larger number of movements

a given time, but not an increased force or range of movements; there was increased speed without effectiveness. The alcohol was absorbed into the system alcohol acted upon the brain and spinal cord much in the same way as the products of fatigue, by dulling mental activity. With alcohol, as with other drugs, there was individual idiosyncrasy; in some persons it induced degenerative changes more rapidly than in others, but from these degenerative changes total abstainers were not altogether exempted. Long before these changes were established, however, repeated imbibition of alcohol had been slowly deranging the functional activity of the higher centres of the brain, whereby co-ordination of the muscular movements had become impaired, and the response of these centres to incoming stimuli less prompt. This condition of the nervous system underlay many of the accidents which occurred in factories and shipyards, and for these, therefore, indulgence in alcohol must be regarded as more or less responsible.

No man could do his best, or even any reliable work, after free use of alcohol. If as a result of the gigantic experiment which at present was being carried out in the United States of America that country was likely to secure a world lead in commerce and industry, then, for the sake of our own people and the future of the empire, some changes would have to take place in the drinking habits of the nation.

The Rev. C. F. Tonks (Organizing Secretary of the Council of England Temperance Society) said that the census statistics, just issued, for 1921, confirmed Dr. Mulligan's statements with regard to the close association of temptation suicide with the convictions for drunkenness, and so the relation of alcohol to industrial inefficiency. In 1920 the total number of convictions for drunkenness was 96,000, and in 1919 it was 57,000. In 1921 the number was 77,000, a decline of 19,000 upon the previous year. The figures for deaths from cirrhosis of the liver did not fall in 1921 at the same rate as the figures for convictions. Roughly, when the trade was good and employment brisk, convictions were more numerous than in bad times. In 1921 the figures for employment showed a marked downward tendency, and the days lost by strikes a great rise. The figures for convictions fell considerably below the figures for the previous year in the months during which the great strikes occurred, and also in the regions particularly affected by the strikes.

Professor F. E. WYNN (Medical Officer of Health, Sheffield) said that what the Section was really discussing was the effect on efficiency of the abuse of alcohol. Many of them would agree that a certain amount of alcohol could be taken without any interference with efficiency, but beyond that amount alcohol immediately began to impair and finally to destroy the efficiency. Well-intentioned people were often so obsessed with the disastrous effects of excessive drinking that they ignored the social and other benefits which could be derived from the proper use of alcohol. To them alcohol was simply something to be abolished. The prohibitionist ignored the fact that by merely removing the temptation from the weak he was doing nothing to reinforce the infirm will. In the campaign against drunkenness the speaker had found one of the chief obstacles to be the teetotal propaganda which opposed any rational measures for the regulation of drinking habits. He still believed that the true solution would be found in the principle he put forward at the Annual Meeting of the Association in 1908—that the method of licensing could be logically applied to alcohol in the same way as to other commodities; it was not merely the vendor of alcohol, but the consumer who should be licensed.

Sir GEORGE TOULMIN (Preston) referred to the early days of temperance propaganda in Lancashire. To-day, unlike its position as it was years ago, alcohol was on the defensive. No one recommended it for hard labour or keen sport; had been argued that if alcohol were as injurious as it was supposed to be, nature would have eliminated alcohol drinkers. But he presumed that alcohol was only a poison it was "pushed" (in the medical sense), and alcohol was not always "pushed"; moreover, the ranks of alcohol drinkers were continually reinforced by those who had not hitherto taken alcohol. He believed that alcohol drinkers were being continually eliminated, but more facts needed to be ascertained on this side of the question. Fifty years ago a pot-boy used to go round the composing room in the printing office; now it was more likely to be the tea-girl, and that meant a real benefit, a higher level of efficiency, and

a lengthening of productive life. The call for alcoholic refreshment had its origin in the call for intermission of strain, and if the hours of labour were so rearranged that that strain did not arise the habit would cease to a large extent. To the social reformer it was interesting to find that no one to-day advocated alcohol as a means of increasing productivity; the discussion centred around the measurement of its bad effect.

Mr. EBENEZER HOWARD, J.P. (founder, Garden City Association), described the progress of the garden city movement, and particularly the improved health and industrial efficiency at Letchworth, where he had never seen a woman the worse for liquor, and very rarely a man. Housing under garden city conditions would tend greatly to diminish intemperance. The speaker, like Professor Wynne, who had just spoken, was prevented from elaborating his argument by the President, who said that the purpose of the discussion was not to consider what steps should be taken to improve the sobriety of the nation, but to elicit facts, based on experiment or personal knowledge, as to the effect of alcohol on industrial efficiency.

Dr. A. K. CHALMERS (Medical Officer of Health, Glasgow) suggested that the human factor was rather being obscured in the discussion. At the time Lord D'Abernon made his inquiry, three or four years ago, in Glasgow broken time was a serious matter in the shipbuilding yards. On investigating as to the places of residence of the men who were irregular in attendance, it was found that the men who lived near the yards were as a rule steady, while the men whose homes were at a distance were musty. The men who lived near at hand were able to go home for meals; the men who came from a distance had to carry some sort of a meal in their pockets. Every doctor knew that when he gave alcohol to a patient the response was not in relation to the quantity he gave, but to the man's power to metabolize the whisky. One man was able to metabolize alcohol in his body better than another, and this had an important bearing on the problem. Men must not be regarded as entirely alike in this matter of alcohol effect.

ALCOHOL AS A BEVERAGE IN ITS RELATION TO INFANTILE MORTALITY.

BY

J. W. BALLANTYNE, M.D., F.R.C.P.E.,

Physician in Charge of the Ante-natal and V.D. Departments in the Edinburgh Royal Maternity Hospital.

INFANTILE mortality is a sensitive index of the well-being of a community. The higher it is the farther removed from healthful conditions is the life of the population in which it occurs; and in its fall everyone recognizes the record of the application of hygienic measures with success. It is when one comes to try to apportion the degree of blame among the various causes which are at work in raising or in maintaining the infantile mortality rate that one finds difficulty and invites difference of opinion. This is inevitable, because parental alcoholism, for instance, is only one among a number of medico-sociological conditions which influence adversely the lives of infants under a year. Bad housing is another; poverty is another; sexual immorality is a third; and so on. All these unite in raising the infantile mortality in any community; there is a reciprocal continuation and aggravation of one by another. To attempt to fix the part played by parental alcoholism as a cause of infantile mortality is really to try to evaluate an ill-defined segment of a vicious circle. At the same time it may not be worthless to survey the problem; even its mere statement may serve to clarify thinking on the matter.

It will be well, in the first place, to define the sphere of the inquiry. Infantile mortality means the deaths which happen in the first year of life, and it is conveniently expressed by the infantile death rate or the number of deaths in the first year per 1,000 live births. It is impossible, however, to exclude from one's thoughts the deaths which occur at or soon before birth, denominated rather unsuitably the stillbirths. It is true that they are foetal whilst the others are infantile deaths; it is true also that the mechanism by which they are brought about is different; but both these groups of disasters may be caused (directly or indirectly) by parental alcoholism, and one can hardly be considered without the other. Of course

one might go farther and include the early foetal or embryonic deaths which are the inevitable result of abortions; indeed, there is a sense in which sterility, in some at least of its forms, is really the expression of germinal deaths; but the emphasis in the present inquiry is to be laid upon infantile deaths and stillbirths. At the same time it ought not to be forgotten that parental alcoholism is a factor in the production of the earlier ante-natal deaths as well as in the disasters which take place at birth and in the first year of post-natal life, although the results of its action in the former are meanwhile statistically inaccessible.

In the second place, one is thinking in this inquiry not of the consumption of alcohol at long intervals and on rare occasions, but rather of its habitual use to a greater or less degree of excess. Alcohol is so diffusible a stimulant that its irregular and infrequent introduction into the body, whether of the mother or the infant (unborn or born) is followed by little or no change in the tissues (the direct effect); its occasional consumption has not the same dire effect upon the family finances as habitual "soaking" has, and it therefore does not lead to serious depreciation in the home environment (the indirect effect). The evil effects of alcohol upon infantile mortality and upon stillbirths are to be looked for in the case of the habitual woman drinker and in that of the man whose alcoholic habits lead to poverty.

CAUSAL FACTORS IN INFANTILE MORTALITY.

Into the causation of infantile death three groups of factors may enter. In the first place, infants at birth and in the first year of life come under the influence of all the lethal conditions which prevail in post-natal existence. The newborn child finds himself in an environment in which the impact of pathological germs is immediate; they may gain entrance to his body through the umbilicus or by the gastro-intestinal or pulmonary mucous membranes; and by the diseases they produce they may cause his death. Their action will be favoured by many other things, including, of course, improper feeding, exposure to cold, errors in the hygiene of the home, and the like. In the second place, infantile deaths may be due to injuries or infections received during the act of birth. Birth is truly a *janua mortis* to many an infant. In some cases the death is immediate and the child is dead-born; in others it follows later from cerebral haemorrhage and birth infections whose full lethal effect is not reached at once. In the third place, infants may come into the world dead, or die after birth from causes which have been active in ante-natal life. It is true that the foetus *in utero* is extraordinarily well protected against morbid agents, whether these reside outside or inside the body of the mother who carries him; but he is not invulnerable. If the placenta, the dominant organ of ante-natal existence, remains healthy, foetal life and health are not in danger; but if it becomes diseased or if morbid germs begin to pass through it, risks are at once introduced and ante-natal death may follow as the immediate result, or such a weakening of tissues may occur as to prepare the way for infantile death as the later result. It has now to be seen whether alcoholism in the parents acts in any or in all of the ways which have been sketched above—whether, in a word or two, it allies itself with the lethal factors which impinge upon the child in his post-natal, his intra-natal, or his ante-natal life. It will be convenient to begin with the last-named time—ante-natal life.

EFFECT OF ALCOHOL IN ANTE-NATAL LIFE.

Ante-natal life commences far back in the ovum and sperm of the parents, and the agents which adversely affect it have been termed racial poisons. Is there reason to believe that alcohol acts as a racial poison? Experimental work on animals gives a clear reply that it does; from the nature of the case it is more difficult to draw conclusions as regards the human subject.

Professor Taav Laitinen¹ of Helsingfors has experimented upon the seeds of white peas and barley in order to determine whether watering them with alcohol solution had any effect upon germination. He found that even comparatively weak solutions of alcohol checked germination, especially in the case of peas, although they were surrounded with a rather strong protecting skin; and he regarded the term "germ poison" as justly applied to alcohol. An effect produced

upon vegetable germination is, of course, a far remove from what alcohol may produce upon the human embryo; but it is of some importance that Laitinen, who before the war had experimented upon guinea-pigs, should have carried his researches back to the influence of this agent upon life as it exists in plants. The observation completes, as it were, the range of the investigation.

In 1917 the present writer² summarized the experimental work which had been done up to that date by Féré (on the hen's egg), by Stockard and Laitinen (on guinea-pigs), and by Pearl (on fowls). Féré had shown that alcohol injected into the hen's egg in incubation produced monstrosities and non-developments and that these were more numerous as the toxicity of the alcohol was increased. Stockard administered alcohol to guinea-pigs (males and females) for prolonged periods by inhalation; the offspring of the first and succeeding generations were weakly, malformed, and affected with a neurosis resembling paralysis agitans; and the conclusion seemed to be clear that fuming with alcohol permanently injured the germ plasma, that of the male cells being more affected than that of the female ones.

In a more recent contribution (to the International Congress against alcohol at Washington in 1920) Stockard³ gave further results obtained from the study of the descendants of the alcoholized guinea-pigs, according to which the evil effects (abortions, stillbirths, malformations, and neuroses) were progressively less marked in the second, third, and fourth generations; in fact the fourth generation might be better than the original pair, and if crossed with the third generation might give "a very superior pig." The explanation was the destruction of those unable to withstand the effects of the alcohol. It is necessary to remember that these conclusions were drawn from male guinea-pigs.

The effect of Stockard's more recent work is useful, for it is most undesirable to draw exaggerated inferences either in one direction or the other in so vital a matter as the effect of alcohol on the progeny. The same lesson is to be learned from Raymond Pearl's researches upon fowls.⁴ This observer gave ether, ethyl and methyl alcohol to the birds by inhalation for one hour daily. The results were a reduction in the proportion of fertile eggs with an increased power of hatching among the fertile ones, except in the cases where both parents were alcoholized: "treated" males with "treated" females gave 59.2 per cent. infertile eggs, whilst "untreated" males with "untreated" females gave only 23.2 per cent.; the differences in hatching power were slight. Courtenay C. Weeks,⁵ who has carefully analysed Pearl's experiments, believes that they show that alcohol has a selective power upon certain germ cells and that it affects the germ plasma, although in the dosage used the power was not sufficient to produce hereditary modifications. In other words, the alcohol acted to some extent as a racial poison, the effect being always heightened when both parent-birds were alcoholized. Incidentally Stockard's and Pearl's researches yield some slight support for Archdall Reid's theory of the progressive destruction of individuals little able to resist the effects of alcohol and the consequent establishment of an alcohol-resisting race.

When one passes from vegetables, birds, and guinea-pigs to the human subject in the germinal stage of existence it becomes, of course, difficult to obtain direct evidence of experimental status and impecability. Bertholet,⁶ more especially in his later observations, has shown marked morbid testicular changes in drinkers as compared with non-drinkers, and something of the same sort in the ovaries. Kyrle and Schaffer⁶ have supported this conclusion by experiments upon dogs. It is true that tuberculosis has the same effect, and this fact introduces an element of error into some of Bertholet's results; but the relation between alcoholism and tuberculosis is a complex one, and neither Wlassak nor Neild thinks that the tuberculosis factor weakens the main conclusion—namely, that chronic alcoholism has a causal connexion with testicular degeneration.

It is difficult to demonstrate evil effects on the embryo from the use of alcohol by the mother, but so definite are the teratogenic effects of this substance in the case of eggs that it is probable that some teratological productions in the human subject have been due to this cause. In several cases the writer noted the coexistence of either maternal or

parental alcoholism in connexion with the birth of phallic foetuses. The bearing of such observations on a general question which is now under consideration is in the fact that teratological developments lead directly to birth, or, by interfering with nutrition, cause infantile

ing the later months of foetal life it has been shown by x² that alcohol taken by the mother passes through infant, and others have confirmed this view. As a rule a recognizable evil effect follows unless the woman by previous use has damaged the placental tissue, and, of course, has largely depreciated the ova in her ovaries. Whatever be the *modus operandi* the tendency to stillbirths, abortions, and premature labours is increased in the confirmed female inebriate continues to drink in her pregnancies; this was clearly shown by Sullivan⁸ a good many years ago. Bezzola⁹ and Hühner¹⁰ have demonstrated that the conceptions which occurred during times of carnival and vintage were apt to result in the birth of idiots or in actual dead-births. Wallace¹¹ has pointed out that women inebriates with families had an increasing number of stillbirths as they progressed from the first to later pregnancies; the number of stillbirths among the firstborn was 6.2 per cent. as against 17.2 per cent. for the later gestations.

Without multiplying references it is possible to reach the conclusion that in each of the three periods of ante-natal life—the germinal, the embryonic, and the foetal—the tendency to excess in alcohol in either or in both parents is a danger to the new being. Sterility shuts it out from life at the start; abortion brings about a cessation of its vitality; a foetal ante-natal existence; stillbirth is the signal that it has succumbed on the very threshold of its post-natal life; when it does enter the world it passes in weakened condition and is exposed to infantile morbidity and mortality. As Dr. Kirmser¹² has put it: "l'alcool est un danger pour l'enfant dès le stade de cellules germinatives jusqu'à sa naissance." Alcoholism, then, not only lessens the number of children born into the world, but it damages those who survive so that they are more likely to succumb to other things in the first year of life. In some of the recent experimental work there is the hint that to some degree alcohol may have a selective effect upon ova and embryos and foetuses. It has been claimed that maternal alcoholism kills off the weaker of the so-called weeds; but if it does so, then does it not weaken the strong ova, and so reduce them to the grade of the weaker ones, the weeds? It is dangerous to argue that alcohol by killing off the weak ova or embryos or foetuses is benefiting the race; if every killing off of the weak is accompanied by a weakening of the strong the race will gain but lose. Such an argument is really sounding the note of retreat in the midst of the advance of hygiene; the "better-dead" cry is an acknowledgement of defeat—it is a proclamation of pessimism.

EFFECT OF ALCOHOL IN INTRA-NATAL LIFE.

Looking next at the infant or foetus in the intra-natal life—that is to say, in the act of being born—one must recognize that any effect of alcoholism then must be indirect. It is a more or less traumatic act. The full-time strong current can pass through the birth canals without injury; but the infant who has had his tissues or those of his placenta weakened by parental alcoholism, especially if he is also born prematurely, will be far more likely to suffer from or succumb to the pressures and stresses of labour. In this way the number of stillbirths and of early post-natal deaths will be increased. If syphilis be superadded, as is not infrequently the case, the integrity of the foetal organs, and especially of the vessels, will be seriously compromised. Such a foetus may be, and no doubt is, more liable to infections during passage from the uterus. It may be merely a coincidence in New York in 1921 (the first year of prohibition) the stillbirths decreased by 19.7 per cent. as compared with the quinquennium 1913-17; but it is at least suggestive of a new hygienic factor coming into play. One must meanwhile, lay too much stress on it, for the coming prohibition has been synchronized in America with the culmination of a great attempt to reduce infantile mortality by all means.

EFFECT OF ALCOHOL ON INFANTILE MORTALITY.

When one comes to consider finally the effect of alcohol in the causation of death in the first year of life it is obvious that new factors are now at work. There will still be a continuance of the direct influence of parental alcoholism upon the tissues of the young infant, especially if the mother nurses her baby and continues to drink; but the indirect effects will now come to the front in the production of infantile mortality. The infant after birth is in a new environment: he is no longer protected by the placental filter from microbes and from some at least of the toxic or toxinogenic agencies which may be in his mother's blood, but is as open to their attack as anyone; he is subject now to the impact of physical agencies, such as heat and cold and injury; and errors in diet and defects in nursing all work their way with him—and how disastrous a way it may be everyone knows very well. In other words, the child is now at the mercy of the secret allies of alcoholism as well as being still the victim of that open enemy, the drinking habits of its parents, which has already weakened its tissues. Early post-natal life is made more rigorous for the infant by the action of these allies of alcohol. This becomes abundantly clear when one considers what they are.

In the first place, parental alcoholism interferes with the proper healthy housing of the young. When one or both parents spend money upon drink there is naturally less available for house rent, and so, sooner or later, the family passes into the one- or the two-roomed house. It is not under the circumstances there existing that an infant in arms runs the best chance of passing unscathed through the early months of life. Dr. Maxwell Williamson, the medical officer of health for Edinburgh, has said: "As may be expected, the influence of housing is reflected most rapidly upon the youngest and weakest members of the population." The four wards in Edinburgh which have the largest number of one- or two-roomed houses have the highest infantile mortality; and the ward, amongst these four, which has the fewest one-roomed houses has the lowest rate of the four. Further, the three worst wards have the public-house in prominence, possessing a very large proportionate number of licences to the population. Here, then, is seen alcohol in alliance with bad housing and overcrowding.

In the second place, drinking habits in the parents destroy health conditions in the home, whether it be a one-roomed, a two-roomed, or a many-roomed house. The National Society for the Prevention of Cruelty to Children has of recent years provided word pictures of the life in such houses which are hardly to be believed, so terrible are they. Sir John Kirk¹² has quoted one of these descriptions, and it is reproduced here in an abbreviated form:

"The windows are broken and stuffed with rags; the walls are filthy; the beds, where there are any at all, are filthy and rotten; the odour of the rooms makes a visitor sick and faint. On the floor lies somebody drunk. On the table lies a beer-can; and about it half-naked children stand perplexed, pale, hungry, and ill. . . . Their skin is alive with vermin. Their heads are sore with festering. There is no food in the cupboard. The monotony of their existence is weekly broken by frenzies at midnight. . . . Baby is flung at the wall. Mother is felled with a chair. Sleeping youngsters are dragged from their bed, and, amid cursings and screams, the Sunday morning begins."

The young infant in such a "home" has a poor chance of surviving; every infantile malady has a better chance of proving fatal there; diarrhoea, bronchitis, the exanthemata, and whooping-cough all become more dangerous in such an environment.

In the third place, all accidents to child life are increased when drinking habits are found in the parents. There is, for instance, the overlaying of young infants, with its sinister frequency of occurrence on Saturday nights; Dr. Mary Seharlieb¹³ attributes this week-end frequency to the receipt on Saturday of wages and to the remission of work on the Sunday—conditions which favour drinking in the parents. But overlaying is only one of the many accidents which are apt to happen to infants in the lessened safety of the drunkard's home; there is the risk of fire, and other casualties. An intoxicated mother is as safe a guardian for a young infant as an insane one.

In the fourth place, the venereal diseases often reinforce the destructive effects of alcoholism in child life. The direct

influence of syphilis on ante-natal existence is well known and shows itself strikingly in abortions and stillbirths; but it also extends its unhappy power to the first year of life, and by producing prematurely born infants who are congenitally weak it increases infantile mortality. Gonorrhoea whilst less death-dealing is apt to lead to congenital blindness. It is unnecessary to state that the venereal diseases are more commonly met with in alcoholics than in the general body of the population.

In the fifth place, the young infant is in danger from the evil effects of the disturbance of feeding which accompanies neobolism. The daughters of alcoholics are often unable to suckle their babies, and so in the early weeks of life artificial feeding has to be resorted to. If the mother herself is given to intemperate habits the details of bottle-cleaning, etc., are carelessly performed or omitted altogether, with ill consequences to the infant. Even when the intemperate mother is able to nurse she is only too likely to do so with irregularity and carelessness. In one respect there has been in recent years a marked change in belief and habit: it is no longer regarded as necessary that the nursing mother should consume alcoholic beverages such as stout in order that there may be a plentiful supply of milk in her breasts, and the custom of taking such drinks in the puerperium and lactation time is in abeyance. It is now accepted that the best milk producer is milk itself or milky foods.

In the sixth place, illegitimacy is not infrequently found allied with intemperance, and it is now a commonplace of statistics that the mortality (after the first month) amongst illegitimate babies is far higher than that amongst those born in wedlock; this is true both of infantile mortality and also of the stillbirth rate.

CONCLUSION.

From all that has been brought forward the place of alcoholism in the vicious circle of causation of stillbirths and infantile deaths has been only too surely established. An alcoholic ancestry is no blessing, but quite the reverse, to the child *in utero* or after birth. Even when the ovum and the sperm escape infertility the embryo is apt to suffer from malformations, and the foetus is endangered when the placenta has been damaged; if the infant is spared the effect of the trauma of birth he comes into an environment in which the influences which I have called the allies of alcohol are at work, and bad housing, overcrowding, bad hygiene in the home, the risk of accidents, the dangers associated with illegitimacy, the disturbance of breast-feeding, and the impact of the venereal diseases, all combine with inherited weakness of tissue, and possibly also with prematurity of birth, to increase infantile mortality. It is no unimportant segment of the vicious circle which is due to alcoholism. As has already been said, the evaluation of this alcoholic part of the circle is impossible; but it may be safely believed that it is not inconsiderable, and that between it and the other segments of the round there is reciprocal continuation and aggravation.

PROHIBITION AND INFANTILE MORTALITY.

The whole world is at the present time occupied in the watching of prohibition, the great medico-sociological experiment which is being carried out in the United States of America. From the point of view of alcohol in relation to infantile mortality it is, of course, an attempt to cut the vicious circle of causation. Some of the prohibitionist press already claim that great benefit has accrued. One must be exceedingly careful about drawing deductions. It has to be remembered that although the eighteenth amendment to the Constitution was ratified on January 29th, 1919, the law did not come into effect till a year later; that before the amendment there were individual States where the use of alcoholic liquors was prohibited; and that at the present time there are only about 3,500 inspectors acting for its enforcement. Miss Ellen C. Babbitt, the Research Editor of the American Child Hygiene Association, has pointed out these facts to me. One has, further, to remember that for the past few years a great crusade has been going on in America, just as in this country, for the saving of child life, and that considerable reductions in infantile mortality have been from time to time recorded. Thus, Mr. Louis I. Dublin, the statistician of the Metropolitan Life Insurance Company of New York, has drawn my attention to the fact that 1920 showed a very remarkable

decline in the infant mortality rate; in the New York State figures for 1921 there is a further satisfactory fall; but to ascribe this continuance in the fall to prohibition is surely to invite sharp criticism. Yet that is what a prohibitionist paper is doing. To quote *The American Issue* (May 6th, 1922):

"Babies had a much better chance in dry 1921 than in the wet quinquennium (1913-1917). Deaths at birth decreased 7.8 per cent.; stillbirths, 19.7; deaths of children under five years, 31; under one year 23.5; . . . in deaths due to congenital debility and malformation 21.2 per cent."

The writer has no doubt in his own mind that prohibition, by lessening the allies (secret and open) of alcoholism, will cause a fall in infantile mortality; but he would be the last to claim that the statistics of New York, where by the way enforcement is believed to be specially defective, for the year 1921 represent the effect of the stoppage of alcoholic habits. One must never forget the fact of the vicious circle; just as many maleficent things combined to keep up a high infantile mortality, so many beneficent things, including the restriction of drinking habits, will work together in drawing it down. To claim a premature victory for prohibition on insufficient, on erroneous grounds would deal a blow to all real efforts to check infantile mortality along these lines. At the same time the writer has no hesitation in predicting that American prohibition will yet be seen to be one of the factors in lessening infantile mortality as well as stillbirths in the United States, and in all other countries which may follow in her wake.

ALCOHOL AS A SELECTIVE AGENT IN THE IMPROVEMENT OF RACIAL STOCK.

BY

CHARLES R. STOCKARD,

Professor of Anatomy, Cornell University Medical College, New York City.

It gives me pleasure to have the opportunity of presenting to the British Medical Association some of the recent results of a long series of experiments on the influence of alcohol in development and inheritance. I am also glad to submit a simple scientific analysis of these results in order to dispel certain misinterpretations and exaggerations which have resulted from a popular exploitation of my findings by propagandists. The experiments were begun in 1909 in connexion with a series of studies on the modification of embryonic development. The author had no interest whatever in a sociological problem, and alcohol was used simply as an effective chemical substance easily administered to the material studied. A number of substances other than alcohol were used with similar results, but standard solutions of these were not so readily prepared and were not in all respects so favourably adapted to this work as were different strengths of alcohol.

By directly subjecting certain species of eggs which develop outside the body of the mother to a great number of chemical and physical treatments it was found that definite developmental modifications could be induced. The results were not specific for any given chemical substance but depended more directly

upon the developmental stage at which the embryos were subjected to the effective treatments. The developing eggs of marine fishes, in most instances those of *Fundulus heteroclitus*, a minnow of the eastern coast of the United States, were subjected to a graded series of alcohol solutions for various lengths of time during different developmental stages. By this simple experiment almost all known types of abnormalities were induced and the history of their development could be studied and analysed.

When eggs were placed in water containing from 1 to 5 per cent. of ethyl alcohol their rate of development was considerably inhibited and in the stronger solutions almost stopped. On later returning these eggs to the usual sea-water environment development was resumed at a normal or almost normal rate. Nevertheless, the arrests which had been experienced caused in many of the eggs the entire suppression of development, while in others the development of many organs and parts were greatly modified. The embryos developed abnormally and were monstrous in form.

An important fact to be noted is the great individual variation in the way the eggs react to the solutions. When any lot of one hundred eggs are examined after these treatments it will be found that a certain percentage of them are developing perfectly normally, as if these had entirely resisted the effects of the treatment; others are only slightly affected; others exhibit more marked modifications; and a number of the eggs have actually been killed. It is thus seen that the effect of the treatment varies with the hardness of the egg. The poor eggs which would have, under usual conditions, developed into weak embryos are eliminated by the treatment, those of low average resistance are injured, while the particularly fine eggs are apparently not affected and live to hatch as vigorous young fish. This variable response occurs when eggs are treated with a sublethal dose of any chemical substance, and it is in no sense a peculiar reaction to alcohol.

Another fact that should be fully recognized in drawing general conclusions from the responses of these embryos to alcohol is that exactly the same injuries and developmental deformities are readily induced by the use of a great number of other chemical stuffs, and also by unusual physical conditions. The fact that such deformities are experimentally produced in embryos by the application of alcohol does not in any sense demonstrate that human deformities have been induced by a similar cause. The amount of alcohol in the solutions to which the eggs are subjected is greater than could be tolerated in the human blood stream. It is also a fact that common salt (sodium chloride), sugar, and many other constantly used substances in human food are equally as effective in inducing the same types of developmental modifications in these eggs as is the application of alcohol. The fact that an experimenter may use an effective dose of a certain substance to induce developmental disturbances has no direct bearing on the question of the use of this substance in very much smaller amounts by man or other animals.

These results should be considered in an impartial manner and should not be distorted for one purpose or another in a discussion of the use of alcohol by man. I can only say, as an embryologist, that the experiments give no certain proof that alcohol has ever caused abnormal development in the human embryo. Neither do they prove that it may not, except in so far as the doses here necessary to induce an effect are greater than we have reason to believe ever exist in the human body. One may ask, Why, then, were such experiments performed, and what is their value? The purpose was to analyse embryonic development by a study of the origin and differentiation of embryonic organs under modified and abnormal conditions.

The readiness with which structural formations may be modified in these externally developing eggs led me to attempt similar modifications in the internally developing embryos of mammals. With this end in view a series of experiments begun twelve years ago with guinea-pigs has been followed and expanded up to the present time. The records in this study now cover several thousand animals of pedigree stock, and probably no comparable experiments with mammals have been followed through so long a time with so large a number of individuals. The experimental method employed has been a daily inhalation of alcohol fumes up to a point of intoxication for the guinea-pigs. This method and the immediate effects of the treatment on individual guinea-pigs have been fully

described in several publications. Dr. G. N. Papanicolaou has constantly been associated with the author in this work during the last eight years of the experiments.

The original purpose of simply affecting the embryo *in utero* soon became of secondary importance. Early in the work it not only seemed possible to affect the developing embryo by treatment of the pregnant mother, but it was also found that the spermatozoon of the male parent could be affected so as to modify the development of a normal egg with which it united in fertilization. The problem then assumed a broader aspect.

When the female mammal is treated with any injurious substance either before or during pregnancy the offspring may be injured in two different ways. In the first place, the strange chemical substance in the blood of the mother might pass directly through the placental membranes and act on the developing embryo, in much the same manner as do chemical solutions on the externally developing egg; or the foreign substance might disturb the metabolism of the mother to such an extent as to interfere with the proper supply of oxygen and food to the embryo. Under any condition this is an action on the developing embryo itself.

The second possibility in treating the female mammal is an injury of the ovarian eggs, the germ cells as such. This case, however, is difficult to differentiate from the first since the question always arises whether the effects of a treatment on the mother might not have persisted and acted upon the developing embryo *in utero*. Thus with the treated female it is difficult to attribute the abnormal development to an injury of the egg cells before fertilization rather than to an environmental influence acting on the embryo.

The treatment of the male, on the other hand, is a crucial test of injury or modification of the germ cells. On breeding treated males with normal females, abnormalities in the resulting offspring can only be attributed to the affected spermatozoa. With these general statements in mind we may proceed to a statistical presentation of the results of alcohol treatments on the progeny of the guinea-pigs.

I shall first present a demonstration of the fact that the treatments do actually produce effects on the offspring. In Table I records are given from normal animals paired alternately with normal and alcoholic mates. The first two columns show that when the same 35 normal male guinea-pigs were mated 81 times with normal mates and 81 times with alcoholic mates

TABLE I.—Alternate Matings of Normal Animals with Normal and Alcoholic Mates.

Defective ...	0	11 5.95 %	0	9 4.97 %

the records were widely divergent. The 196 young born from the normal combination showed a mortality during the first three months of only 22.96 per cent. and none of these offspring were defective. (The guinea-pig is mature at about 3 months old.) Of the 185 young produced by the same normal fathers mated with alcoholic mothers 56.6 per cent., or only a little more than half of them, lived to reach maturity. The mortality here was about twice as great as from the untreated mothers, being 43.3 per cent. as against 22.9 per cent. Eleven of these offspring, or almost 6 per cent., were structurally defective, while none from the normal combination showed any such defects.

The two columns on the right of Table I contain still more striking data, since these show conclusively that the male

germ cell or spermatozoon is definitely affected by the treatment. In this case 44 normal mothers were mated alternately with normal males and treated males. The same normal mothers produced all the offspring, but those recorded in the third column were sired by normal fathers, and those in the fourth column were sired by alcoholic males. The 77 normal matings produced 195 young, and there were only three failures to conceive. Eighty-one matings of the same females with alcoholic males gave only 182 young, and over 12 per cent. of these matings failed to result in conception. There was a mortality of only 17.4 per cent. among the offspring from the normal matings, while the alcoholic fathers sired offspring that suffered a mortality twice as high, being 35.1 per cent. Nine of the offspring from the alcoholic fathers were defective, but none from the normal sires.

This discrepancy between the records of offspring from the same normal individuals when paired with normal and alcoholic mates clearly demonstrates an injurious action of the experimental treatments on the germ cells of these mammals. We may further analyse very briefly in the following tables the action of these effects during later generations. In Table II are given the records of animals occurring in the different generations of the alcoholic stock. Section I contains data from the control or normal lines. These animals are of the same blood lines as the alcoholic stock—brothers and sisters and parents and offspring are in the two groups, and actually in cases the same individuals have first been used in the control and later in the experimental groups. There can be no doubt that any original defect or weakness that may have been in the stock from which the alcoholic animals were derived must also have been in the control stock, since the stocks are in all cases actually the same. All records in the present tables are of pedigree animals from thoroughly known blood lines and relationships. There is no inbreeding in either the control or alcoholic lines. It is as certain as experimental evidence can be that any differences between the records of the control and the treated groups must be attributed to the action of the alcohol treatment, since this is the only element of difference existing in the life histories or experiences of the two groups of guinea-pigs.

The records for the control show that the stock is strong and well. The average litter of young is about three, and the average litter weight is 188.85 grams at birth. The data from 506 control individuals show a total mortality before reaching maturity of only 22.72 per cent. One familiar with breeding guinea-pigs will recognize this as a very good record, far better than usual. In the last two columns of the table the total mortality has been divided into pre-natal and post-natal deaths. The absorbed embryos, premature births or absorptions, and stillborn young make up 53.91 per cent., or about half of the total mortality. The post-natal mortality, under three months of age, was 46 per cent. of the total. This equal division of pre-natal and early post-natal mortality is the normal expectation for these animals. But Section II of the table shows that in the alcoholic generations the pre-natal is double the post-natal mortality, and among the F_1 animals in Section III the pre-natal mortality is more than two and a half times greater than the post-natal.

Table II shows the size of litter in which the individuals occur. This is important, since animals born in large litters are at a disadvantage as compared with those born in small litters. The control section, for example, indicates that animals born in litters of two have a total mortality of only 17.5 per cent., while those born in litters of four suffer a mortality almost twice as high, or 33.3 per cent. The average litter size in the alcoholic groups is smaller than among the control. This fact actually benefits their records and the mortality readings are corrected for the differences in litter size in the total mortality line of the table.

Considering the successive generations it is seen that the offspring from directly treated parents present the poorest record of all. Almost 43 per cent. of their young are lost before maturity, and actually 70.3 per cent. of these are either absorbed as early embryos, aborted prematurely, or are stillborn. When these F_1 animals occur in small litters their chances for survival are greatly improved, so that of those occurring two in a litter only 28.5 per cent. died, but of those in litters of four 73 per cent. died. This fact conveys an idea of the great advantage possessed by members of the small litters. These are actually

partial litters, the hardy survivors of an originally larger litter. When the records of the F_1 animals are corrected for litter size their mortality is about double that of the control.

Many of these F_1 animals are defective and many are sterile; thus only the best of them are available to give rise to the following generations. Yet in spite of this partial elimination of the defectives enough effect has been produced by the alcohol treatment on all individuals to cause the grandchildren to show an unfavourable record. When the records of the 747 animals of Section IV are compared with the control section the influence of the alcohol treatment is seen to be transmitted by the F_1

ration, although they had not been directly treated. The children of treated grandparents, the F_2 group, show a record closely comparable with that of the offspring of directly treated animals. The pre-natal mortality is here just twice as high as the post-natal, and the total mortality 1 per cent. greater than among the control.

Again, among the F_2 animals there are defective and sterile specimens. Thus another individual elimination and selection occurs in this generation and only the most vigorous individuals of the group are left to breed. These more vigorous specimens in many cases mated with normal stock, so that the records of animals descended from treated great-grandparents are somewhat improved, yet the litter size is small and the mortality for 287 such animals is 40 per cent. higher than among the control.

Finally, the constant elimination of the defective individuals through three generations and the matings with normal stock of animals descended from alcoholized great-great-grandparents which are superior in their records to the normal control animals. They are born in smaller litters than the control, even when this is taken into account their mortality is actually only 64 per cent. of that of the control animals. Such animals actually have a total mortality before the age of maturity of only 13.5 per cent.

The fact that the F_4 animals from alcoholic ancestry are inferior in record to the control is a point of actual significance. There can be no doubt that the offspring from treated parents are decidedly inferior as compared with the control; and further, that their offspring, or the progeny from treated grandparents, are also evidently inferior, but during these generations individual selection is taking place through the elimination in the race of the defective and sterile specimens. This selection finally brings out a group of unusually strong specimens in which all the weaklings have been eliminated, and although they are not quite so productive as the control, their offspring show a record superior in vitality.

Should one desire to apply these experimental results to the human alcohol problem, it might be claimed that some such elimination of unfit individuals had benefited the races of Europe, since all of the dominant races have a definitely alcoholic history, and the excessive use of alcohol was decidedly more prevalent three or four generations ago than it is to-day. That is, certain families that were alcoholic three generations ago have not been excessively so in the more recent generations.

Further evidence of significant importance regarding this selective action and the elimination of defective individuals is obtained in Table III. This table was arranged to determine whether the alcoholic treatment of only male ancestors was as injurious to the offspring as the treatment of female ancestors.

The first three sections show the records of offspring from directly alcoholized parents. In Section I, when only the father was treated, the average litter was small, the total mortality was 71 per cent. higher than normal, and the pre-natal deaths were almost two and one-third times greater than the early post-natal mortality. The entire reaction is typical of the alcoholic line.

In Section II, where only the mothers were treated, the records are considerably worse than the records from the treated fathers. The average size of the litters was somewhat larger than from the treated males, but the actual litter weight of these larger litters was less. The individuals from alcoholic mothers are small at birth. The mortality among these offspring was 61 per cent., or almost two and a half times higher than among the control. For comparison, if we call the mortality of control animals 100, then the mortality of the offspring from treated fathers is 171, and from treated mothers 243.

Section III shows that the treatment of both parents does not greatly alter the results which would have followed if the other alone had been treated. The total mortality is actually a little lower, but this is probably due to the small number of individuals recorded in this column.

The last three sections give the records of 747 descendants of the survivors from the first three sections. These records indicate the degree of transmission of the induced defective conditions. They supply the most striking data pertaining to the selective action which took place in the first filial generation of the alcoholic race to eliminate the defective individuals.

The records show the mortality to be highest among animals descended from treated males. And among such animals the

pre-natal mortality is more than twice as great as the early post-natal mortality.

Animals having only female ancestors that had been subjected to alcohol treatment show in Section V a lower mortality than those from treated male ancestors. Here the pre-natal and post-natal mortalities are almost equal. At first sight it would seem as though the treatments had acted more severely on the male than on the female germ cells. None of the animals in the last three sections are the offspring of directly treated parents, so that all inferiority must be attributed to the action of the treatment on the ancestral germ cells. The superior record in the female treated section is, however, no doubt due to the more rigorous elimination of defectives that occurred among the F_1 animals in Section II.

The last section shows that the group of animals recorded as descended from both treated male and female ancestors have

also a bad record as compared with the control data shown in Table II: The results in this section are at first sight somewhat misleading, since they are better than those from only male ancestors treated and are worse than those from only female ancestors treated. But here again the elimination which took place in the first generation has ensured to some extent the quality of the survivors, and makes it improper to compare the total results as an actual measure of the original effect induced.

We may briefly compare the data in the two sets of sections to demonstrate the consequence of the severe elimination of unfit individuals which is taking place in these experiments. In the first three sections the size of litter was smallest from treated fathers, larger from treated mothers, and largest when both parents were treated. In the last three sections the litter size is exactly reversed; it is largest for those with male ancestors treated, smaller when female ancestors were treated, and smallest among animals with male and female ancestors treated. The mortality records show about the same relationship. Among the offspring of directly treated parents the mortality was lowest from treated fathers—171 against 100 as normal; the mortality was very high from treated mothers—243 against the normal 100; and high when both parents were treated—213. The descendants from the treated males which had suffered the lowest mortality in the first generation subsequently show the highest mortality in later generations—188 against 132 for descendants of treated females, and 165 for the descendants from both treated males and females. This simply means that when the action of the treatment is severe on the first generation, as was the case when the mothers were treated and the highest mortality among offspring obtained, only the comparatively hardy individuals survive. Their descendants later show a superior record in comparison with the descendants from treated males among which the eliminations in the first generation had not been so severe. Taking the mortality records of the first three sections and writing under them the records from the same lines in the last three sections we find that when the mortality is high in the first generation it is low for subsequent generations, and vice versa:

171	..	243	..	213
188	..	132	..	165
359	..	375	..	378

If the two numbers in the three sets of mortalities be added together the sum in each case is about the same.

When we consider the welfare of the race or stock rather than that of the individual it is found that the descendants of those groups of animals which suffered the highest mortalities and withstood the most rigorous selection are superior in quality to the descendants from the groups less severely affected. This individual selection furnishes a great advantage to the later generations, as is shown by the superior quality of the F_2 group of guinea-pigs in the Table II.

DISCUSSION.

Professor LOUISE McILROY, M.D., D.Sc. (University of London), said that it was extremely difficult to dogmatize on this subject of alcohol, for the reason that it was so bound up with other questions, such as problems of illegitimacy and venereal disease, all of which meant a bad environment for the child after it was born. It was extremely difficult and dangerous to say that a particular condition was due to alcohol, and another condition was due to venereal disease, because they were all so much bound up together. But she wished to impress upon the Section the enormous importance of knowing what the condition of the mother was before the child was born. She had not the slightest hesitation in saying that if she were given the responsibility of looking after the children of the country, she would rather surrender the responsibility of looking after the children after they were born than give up her control of the conditions for the nine months previous to their birth. More pre-natal care would mean greatly lessened mortality after birth. She had been greatly disappointed to hear one speaker in the Section of Obstetrics say that it was extremely difficult to get ante-natal clinics formed in Glasgow. Ante-natal clinics offered one of the solutions of the alcohol problem. Alcoholism in the mother during pregnancy must have an enormous effect on the child. How could a mother soaked in alcohol be expected to bear a healthy child? The child came into the world with what was known in the insurance

companies as a "bad life." This affected the State in two ways. In the first place alcohol prevented conception. Alcoholic women were very frequently sterile. If conception occurred, it was difficult to carry on the foetus to full term. During pregnancy abortion, which was a terrible wastage of child life, was very liable to take place. The placenta was poisoned, and, naturally, the child was poisoned also. Until there was some means of dealing with abortions, like their notification and registration, it would never be known how great a wastage of child life they represented. This was a most important question for the State. If the population was to be kept up sterility must be prevented by protecting the health of the potential mothers and of the potential fathers also. The effect of alcohol on the sperm or male cell must be guessed at to a certain extent. It was possible that alcoholic parents had devitalized children. She would not dogmatize on that point, but she did know that maternity cases in which the women were habitual drunkards gave those in charge of them enormous anxiety. In alcoholic cases, where the muscles were poisoned with the toxæmia, those in attendance were compelled to have resort to all kinds of obstetrical operation, and with every operation the chance of the child's life was diminished, and of its health if it survived the ordeal of birth. If the necessity of operative interference in births was to be diminished, those interested in the question of alcohol must get the State and the local authorities to establish and encourage ante-natal clinics. To her own mind foetal welfare and foetal mortality were far more important subjects than infant welfare and infant mortality. Ordinarily the giving of an anaesthetic such as chloroform or ether in a case of labour was fairly safe, but in the alcoholic subject it was dangerous, because the whole of the organs were clogged with the alcoholic poison. From the sterility among alcoholic women, and from the frequency of abortions and the difficulty of childbirth, one could see nature to a certain extent putting forward her efforts to reduce the number of children entering the world from alcoholic stock. Here some of them were faced with a moral problem which affected their conscience. Were they themselves to take any part in reducing the number of these children born into the world? This raised the whole question of the segregation of the people who were unfit for parentage, and how, if at all, they were to be prevented from propagating. The present-day teaching was that every individual should have liberty in this matter. But were men and women who were chronic alcoholics to be allowed to propagate children for the State to look after? A great deal of propaganda was going on at the present moment, which from the medical point of view, apart from the moral point of view, was extremely dangerous, calling for an artificial diminution of the birth rate, and she believed that this propaganda might produce very serious effects during the next few years if the public were not warned in time. But the production of devitalized children by alcoholic parents was just one of the things that would furnish that propaganda with its arguments.

Mr. THEODORE NEILD (Leominster) criticized certain points in, or omissions from, Dr. Stockard's paper, particularly the absence of any statement as to the direct effect produced upon the animal. He had had the great privilege, however, of meeting Dr. Stockard at Cornell University, and was shown by him some of his animals, which did not appear after vaporization to show the least sign of physical deterioration. He had had the opportunity of speaking with another investigator on this subject, Bertholet of Lausanne, who told him that in the case of animals which had been vaporized the children of an alcoholized father had a certain progeny, the children of an alcoholized mother a rather larger progeny, and the children of an alcoholized father and mother a slightly higher progeny still. This did not quite agree with the statement that children of alcoholized parents were less fecund.

Dr. R. B. McVITTIE (Dublin) said that infant mortality was very largely the result of ante-natal conditions, and it was difficult to form any correct estimate of the effect of alcohol, because the parents' statements had to be accepted, and alcohol did not make for truthfulness. Therefore statistics were likely to be even more misleading in these cases than they were under more favourable circumstances. His opinion was that alcoholics gave birth to a greater number of children than a corresponding number of temperate people, but that the death rate amongst those children

much higher. But the whole subject seemed to be med up in one word—metabolism. This most elaborately complicated process was influenced in the human body by such an extraordinary combination of social, biological, emotional, and hygienic circumstances that as very difficult indeed to allot the correct value to any individual factor. Some experiments on plants which the speaker had carried out seemed to be of some interest in connexion. He grew six plants under exactly the same circumstances: two tobacco plants, two geraniums, and two clematis. He watered one specimen of each group with a measure of water, and the other with the same measure of water together with a teaspoonful of whisky. At the end of the week the "whisky plants" looked decidedly greener and healthier than the "watered plants." He then increased the dose to two teaspoonfuls to the dose, and at the end of the second week the "whisky plants" were still the more flourishing and slightly the taller. Then came a sudden frost, and within about four hours the "whisky plants" were killed, and next morning were dead, while the other plants had had no whisky were quite well and lived for many months. Demonstrations on the influence of alcohol on the metabolic rate would be helpful in clearing away some of the doubts of opinion, which were often the result of the personal rather than of evidence which scientific observers would accumulate.

Closing Remarks by the President.

THE PRESIDENT OF THE SECTION (Dr. Fothergill), at the end of the four discussions, said that it was not easy to sum up in the chair without tending to reiteration. The members of the Section had listened, much to their advantage, to artists, scholars, and social workers, all of whom were well equipped and competent to speak upon the subject selected. As far as possible the discussion had been limited to defining what extent, if any, the use of alcohol as a beverage affected physical and mental health, industrial efficiency, and autolite mortality—all of them important social problems, though they by no means exhausted the list. As was to be expected, the voice of the advanced school—the progressive school—had been heard. What would become of any social problem if such a school ceased to exist? The rest of them were debtors to the enthusiasm of that school. There seemed to be two classes into which social reformers interested in this question could be divided: There were those who concentrated on the individual and those who concentrated on the surroundings of the individual—that is to say, there were those who were interested in the environment of the individual character and those who were interested in the environment of circumstances. The medical profession of necessity tended to join itself with the latter class, and it would be from that aspect that its co-operation would be maintained. Given active, intelligent, preventive social work, which led to the improvement in the environment of circumstances, one might reasonably hope that the environment of the individual character would at last have its chance. Just as it was the case with individuals, so with groups, classes, and also with nations—no two were exactly alike. To each there had been given a unique personality, and this was essential in order to fulfil its unique part in the social venture. The privilege, therefore, of a group or class, especially educated to express an opinion, carried with it great responsibilities. It should be recognized that there was lying in this moment ready to the hand of each such group or class something to be done with regard to the use of alcohol as a beverage, which something could not be done by any other group or class, and if it were not done a fully satisfactory solution of the problem would be prevented. Was it, therefore, too much to appeal, whilst the Association met in Glasgow, to employers and employees, to all groups in the Church, to the other learned professions, and, in fact, to all who were striving to perfect our empire, that they should busy themselves with at least the aspect of the question with which they were specially qualified to deal? Could they not all come together, there and then, to try and discover what preventive work they could combine to do? And, having decided on it, could they not take steps to secure informed and organized public opinion in its favour?

In conclusion, on behalf of the British Medical Association, he thanked the readers of papers as well as those who by their contributions to the discussion had helped toward what might well be considered a most successful double session. Especially he wished to thank the two honorary secretaries

(Dr. Alex. Forbes and Dr. David McKail) for many months of strenuous, anxious, and unselfish work. (Applause.)

Before the meeting concluded the Rev. C. C. WEEKS proposed and Dr. J. W. BALLANTYNE seconded:

That the Council of the British Medical Association be requested to assist in the promotion of further inquiry into the effect of alcohol taken as a beverage on the individual and the community.

This was carried unanimously.

The Sections.

BRIEF SUMMARY OF PROCEEDINGS.

(Continued from page 218.)

SECTION OF MEDICINE.

Thursday, July 27th.

THE Chairman, Dr. Hawthorne, in the course of a few introductory remarks, said that the subject for discussion—exophthalmic goitre—was one of great importance, not only to the physician, but also to the surgeon, ophthalmic surgeon, laryngologist, endocrinologist, and general practitioner. Professor G. R. MURRAY then read his paper on exophthalmic goitre. He began by urging the importance of a more full consideration of the prevention of the disease. In dealing briefly with the general pathology of the condition he discussed the possible cause of exophthalmos. The three main views as to its causation which had been put forward were those of (1) vascular engorgement, which, in his opinion, had little to support it; (2) increase of orbital fat; (3) overaction on the part of Müller's muscle. This last view was not, in Professor Murray's opinion, a probable one, since the fibres of this muscle were very feeble, the muscle too far from the globe to produce proptosis, and, furthermore, if it did, it should, from its anatomical position, do so in an upward and forward direction. He inclined to the second view—namely, that an increase of orbital fat was the most likely cause of the proptosis. He next dealt with some of the etiological factors. In a series of 300 cases he had found that the disease occurred more frequently in women—to the extent of three to one, but it was interesting to note, he said, that former statistics had shown a proportion of eleven to one, indicating, therefore, that sex was not as important a factor as was hitherto thought. He pointed out that a family history was sometimes obtained, and instanced a number of cases to support this. Nervous strain and shock were certainly factors, but the condition seldom resulted from physical injuries. He then went on to discuss the relationship of simple goitre to exophthalmic goitre, and urged the importance of treating many of the simple cases along the same lines as would be adopted in Graves's disease. He emphasized the importance of recognizing the symptoms of exophthalmic goitre in its early stages, as treatment, if adopted then, was much more likely to be of value than if the case was one of some duration. As regards treatment, Professor Murray said that almost complete rest was essential at the commencement. It was his practice as regards diet to allow no red meat or extracts, but he was in the habit of giving milk and fats in usual amounts. In discussing the value of x-rays in the treatment of exophthalmic goitre, Dr. Murray emphasized the importance of discontinuing this method of treatment if no improvement had attended it after six months' trial. Radium he had found useful in many cases, but there was danger in acute cases. Surgical treatment was indicated if medical treatment had failed, if the thyroid gland was much enlarged, or if time was an important factor to the patient; but the risk of operation could not be forgotten.

Dr. C. M. Wilson (London) asked why it was that more progress was not made in the subject of exophthalmic goitre. He himself thought it was because all discussions centred round late cases, whereas attention should be riveted on the early recognition of the disease. He urged the importance of basic metabolic measurements in the early diagnosis of the condition, and showed several cases on the screen which illustrated the diagnostic value of the basic metabolic rate in relation to exophthalmic goitre. Mr. James Berry said that co-operation between physician and surgeon was of extreme importance in the successful treatment of Graves's disease. He admitted the danger in operative measures, and emphasized the importance of having the patient under personal observation for at least a few days before the operation was performed. He admitted the undoubted

benefit from rest and α rays in many cases, but warned his hearers against carrying on α rays too long. The longer the duration of the disease, the more unlikely was it to be successfully treated at the hands of the surgeon. In acute cases surgery should be avoided during the most acute stage unless there was definite evidence that no myocardial degeneration was present. During remissions of the disease operation gave the best results. Ether in small quantities was, in his opinion, the best anaesthetic; local anaesthesia and chloroform dangerous. Dr. Riddell about 80 per cent. of patients suffering goitre got relief from α -ray treatment. In

some cases the thyroid gland might not show much decrease in size, but the amelioration of symptoms suggested that the α rays had been of benefit. He was in favour of giving fairly long applications at considerable intervals rather than minute doses frequently. He agreed that no good was got from continuing treatment for more than six months. Dr. Purves (South Africa) urged the importance of vaccine treatment in cases of ophthalmic goitre.

Professor David Drummond called attention to the frequency with which the condition of hyporlymphism was present in cases of ophthalmic goitre, and showed specimens from a recent *post-mortem* examination—the patient having died suddenly after operation—in which the lingual tonsil was much enlarged and the thymus gland nearly five times its normal size. This state, amounting to status lymphaticus, would often, he thought, prove to be the cause of sudden death after operation, and an attempt should be made to diagnose it. Mr. Mamourian (Ashton-under-Lyne) said that the longer α -ray treatment was practised the more difficult was the operation for the surgeon. He thought it important that the question of dosage should be in the hands of the physician or surgeon and not in those of the radiologist. Local anaesthesia was, in his opinion, the anaesthetic of choice. Dr. H. C. Tidy asked when exophthalmic goitre could be considered cured. He instanced cases where exophthalmos persisted and the thyroid glands still remained large, but the symptoms otherwise had apparently disappeared. Dr. Tidy also read a communication from Lieut.-Colonel McCarrison dealing with the present trend of research regarding the origin of exophthalmic goitre. Dr. Hawthorne said that the Section was fortunate in having had first-hand information on the subject of exophthalmic goitre, and welcomed the fact that so much emphasis had been placed on the subject of prevention of this disease. Professor Murray then replied and made clear certain points which had been raised by the speakers.

Friday, July 28th.

After a few introductory remarks by Sir Archibald Garrod, who was in the chair, Sir Humphry Rolleston opened the discussion on degenerative diseases of the liver. He began by dividing liver degenerations into two main groups: acute or subacute; and chronic. The main points raised by Sir Humphry Rolleston in his paper were: (1) Tests for functional efficiency of the liver: their scope, limitations, and results, especially in slight and latent degenerations of the liver. (2) The question whether the jaundice occasionally seen in early syphilis, in syphilitic patients after arsenobenzol treatment, and the jaundice of munition workers depended on inherent weakness of the liver, or were due to an additional factor—namely, infection. (3) The explanation of the delayed onset of symptoms in persons previously exposed to the action of poisons, such as trinitrotolene in arsenobenzol preparations. (4) Whether changes in degenerative diseases of the liver were due to failure of the damaged cells to remove from the blood the bilirubin formed elsewhere, or whether the liver cells, as the result of disordered function, shunted the bile pigment into the lymph and blood capillaries instead of into the biliary capillaries. (5) If the anaemia in a hepatic degeneration was due to failure of the liver cells to resynthesize urobilin and iron into haemoglobin. (6) Intrahepatic formation of urobilin. (7) How far the incidence of cirrhosis after hepatitis accompanied by degeneration of the liver cells was obviated by concomitant hyperplasia of the liver cells. (8) Whether the interstitial hypoplasia in cirrhosis was initially a beneficial process. (9) The value of haemosiderinuria in the diagnosis of haemochromatosis. (10) The relation of primary carcinoma of the liver to a previous degeneration and de-differentiation of the liver cells.

Professor Maclean, who spoke next, confined himself chiefly to the tests employed for determining liver efficiency. Such tests differed very materially from those of the kidney

because the functions of the liver were not yet fully understood. We did know, however, that the liver played the chief part in carbohydrate metabolism. The laevulose test was based upon that, and he found it useful as indicating deranged function of liver. The lipase test also was probably useful, but he himself had not had much experience of it. Dr. C. M. Wilson said that the real need was for a test which would give information indicative of liver damage before symptoms were evident. He thought that the laevulose test and the haemolysis test were valuable, though positive results were got in conditions other than those of liver damage. Dr. Spence confined his remarks to a description of the laevulose test, and showed a series of cases on the screen illustrating results obtained with this test in cases of moderate, severe, and extreme liver insufficiency. The ultimate scope of this test was yet to be determined, but even now it undoubtedly served a useful purpose. Dr. McNece stated that a fuller knowledge of the structure of the liver was essential, for as yet it was far from being understood. He doubted very much whether all liver cells were the same. Great advances had been made in the knowledge of one type of cell—namely, the star cells of Kupffer, which lined the vascular capillaries. He demonstrated on the screen slides which showed these cells to be very numerous in the outer third of the lobules; they increased in number after poison had been introduced. He maintained that bile pigment was formed chiefly in Kupffer cells and in the endothelial cells of the splen in man. The extent of jaundice in no way indicated the amount of damage to liver cells.

Professor Muir discussed the three chief factors in the production of jaundice—namely, obstruction to the bile ducts, blood destruction, and damaged hepatic cells. More knowledge was wanted on the part played by the hepatic cells in the production of jaundice. With regard to cirrhosis of the liver, Professor Muir did not agree with Sir Humphry Rolleston that the new formation of connective tissue was purposeful. In haemochromatosis he agreed that fibrosis was the first stage and pigmentation followed. Sir William Willcox spoke on the toxicological aspects of liver degeneration. He reminded his hearers of the great protective function of the liver against oxogenous poisons. He held that the delayed onset of jaundice seen in patients previously treated with arsenobenzol preparations was not due to arsenic, but to the effects of that compound upon the liver itself. Professor Stewart described a series of cases of toxic jaundice which, with two exceptions, completely recovered after certain periods of time; this seemed to indicate that all the cases must have had at one time atrophy of the liver resulting in a fibrosis which was, however, not progressive. He suggested that haemochromatosis might possibly be due, in some cases at least, to congenital defect. Dr. Stuart McDonald spoke of the part played by bacterial infection in the production of acute yellow atrophy. Sir Archibald Garrod, in summing up, said that the subject had divided itself into two main parts—namely: (1) Functional tests on the liver, and (2) formation of bilirubin and the jaundice that occurred in the liver cells. Sir Humphry Rolleston replied very briefly to points raised in the discussion.

SECTION OF MICROBIOLOGY, INCLUDING BACTERIOLOGY.

Thursday, July 27th.

THE bacteriology of influenza was the subject discussed on July 27th. Sir William Leishman occupied the chair on the suggestion of the President, Dr. Buchanan. Dr. Mervyn Gordon first discussed the bacteriology of catarrh, and pointed out that no examination could be regarded as complete until films from its fresh material had been examined by Gram's stain and Giemsa, cultures made on agar enriched with ascites fluid, blood, etc., and when practicable a specimen of the secretion filtered through a Berkefeld filter and the filtrate cultured in Noguchi's medium. He discussed the general properties of filter-passing organisms less than 0.5 of a micron in size, drawing attention to the difficulty of staining them and securing cultures. Dealing first of all with acute coryza, Dr. Gordon recalled that Kruse in 1914 demonstrated the presence of a filter-passing virus in the common cold, and that Colonel Foster confirmed this work and grew an organism in Noguchi's medium from the filtrate of nasal secretions. Passing on to discuss influenza, Dr. Gordon considered that the many negative results obtained by experimental inoculation with Pfeiffer's bacillus and the frequent finding of this organism in other conditions constituted

strong reasons against regarding it as the primary infective agent. On the other hand, Yamanouchi and Olitsky and Gates showed that inoculation of a filtrate of the nasal secretion caused influenza and the virus could be cultured. Dr. Gordon's own observations concerned a sharp outbreak of influenza among the nursing staff of St. Bartholomew's Hospital when fifty-seven nurses were attacked. The diluted nasal secretion was passed through a Berkefeld filter and cultured in Noguelli tubes. In positive cases a cloudiness appeared round the tissue at the bottom after four to six days, and films from this cloud stained with Giemsa showed minute round specks. From 20 cases so examined a filter-passing organism was recovered in 14. Dr. Gordon drew attention to the great difficulty of staining and culturing this virus, but showed several lantern slides of microscopic preparations illustrating clearly the appearance of the organism.

Professor J. McIntosh referred to some work carried out in the winter of 1918-19 when Pfeiffer's bacillus was recovered from 80 per cent. of the patients examined, and found *post mortem* in 75 per cent. of patients dying from influenza. He failed to isolate any filtrable virus from recent cases examined, but produced typical influenza lesions by inoculating cultures of Pfeiffer's bacillus; he therefore still regarded Pfeiffer's bacillus as the primary infective agent. He criticized conclusions drawn from the appearance of "cloudiness" in cultures, since such cloudiness often appeared spontaneously; even if a filter-passing organism could be isolated from influenza cases, there was still no proof that it caused the disease. Dr. J. H. Dible recorded his study of the fermentation reactions of forty-six strains of influenza bacilli, which he found could be separated into several different groups. He obtained the characteristic blood picture of influenza by injecting bacterial toxin, and criticized the work of those who looked upon influenza as caused by a filtrable virus.

Sir William Leishman referred to evidence derived from preventive inoculation with *B. influenzae* vaccine. The results obtained were different in different parts of the world. In two reports presented the vaccine had conferred no benefit, but in a third instance marked protection seemed to have been derived from the vaccination. Professor Ledingham favoured Dr. Gordon's point of view, and criticized Professor McIntosh's results. Dr. Twort referred to the desirability of stating the exact conditions under which filtration was carried out. It was not necessary to use blood for the cultivation of the influenza bacillus, since it would grow well on ordinary nutrient agar in symbiosis with certain soil bacteria. Dr. Fleming remarked on the diversity of agents which might be responsible for initiating a common cold, and Colonel Mackie described the severe epidemic in India, when six million people lost their lives.

Dr. Buchanan recorded an experiment in which a plate was exposed in front of the mouth of an influenza patient, with the result that Pfeiffer's bacillus and pneumococci and streptococci all grew in culture. The case for the filter-passer was strong, but it was necessary to keep an open mind.

In his reply Dr. Gordon agreed that it was proved conclusively that experimental inoculation of Pfeiffer's bacillus could produce lesions identical *post-mortem* with those found in influenza, but were there not other facts behind this? He did not claim that the filter passer was necessarily the cause of influenza, but that it was present, and he appealed for it to be looked for and carefully studied. His filtrations were carried out under a *minus* pressure of 10 to 12 cm. of mercury, the operation lasting only about five minutes. Undoubtedly a filter-passing organism was present: what its significance was we were not yet in a position to say. Sir William Leishman, in concluding the discussion, said that an organized attack on the problem from many different angles was about to be undertaken by the Medical Research Council.

Dr. Andrew Connal read a paper on the development of *Loa loa* in Chrysops, in which he described the development of the filaria from the time of its ingestion by the fly to full maturity. He recounted the technique adopted for catching and feeding the flies and the three phases of development of the filaria and its manner of escape from the proboscis of the Chrysops. Sir William Leishman congratulated Dr. and Mrs. Connal on this brilliant research.

Friday, July 28th.

In opening the Microbiology Section on Friday Dr. Buchanan pointed to the importance of close co-operation between those studying plant and animal bacteriology. Professor H. V. Blackman opened the discussion on similarities and dissimilarities between plant and animal diseases by

showing a series of slides illustrating the manner in which *Betrylis cinerea* and the rust fungi attack plants. The former of these secretes an enzyme which destroys the tissues in advance, the hyphae of the fungus entering directly through the cuticle; the hyphae of the rust fungi, on the other hand, enter through the stomata, and the cells of the plant are not killed but stimulated to fresh activity by the symbiotic relationship which is established. No general body reaction to infection can be demonstrated in plants in response to infection such as that which occurs in the animal body under similar conditions. He referred also to the virus diseases of plants, and pointed out that some of these were known to be carried by insects. On the whole he considered that the dissimilarities were greater than the similarities when plant and animal diseases were considered, chiefly on account of the absence of a general body reaction in plants. Dr. W. B. Brierley discussed the general relationship between plant parasite and host, and declared that in plant pathology the more vigorous host often took disease more readily than the weaker, and the fungus under such circumstances was stimulated to greater activity. The final condition established was usually one of symbiosis. There was, he said, little in common between animal and plant pathology. Professor F. H. Gaiger was of the opinion that the dissimilarities were greater than the similarities when plant and animal diseases were compared. He pointed out how little was known as to how virus diseases were communicated from one plant to another. Dr. Ledingham said that man was particularly resistant to fungus diseases, and Professor Blackman had chiefly considered these. In the field of natural immunity there seemed to be a great deal of common ground, and bacterial invasion of plants had many similarities to human bacterial invasion. Professor Ellis pointed out that plant and animal protoplasm was essentially the same, and if lower forms were compared in each group many similarities must be found. Dr. Buchanan also thought that the similarities were greater than the dissimilarities, and expressed the opinion that a society for the study of comparative pathology and microbiology of plants and animals would serve a very useful purpose. In his reply, Professor Blackman agreed that fundamentally there must be marked resemblances, and that those would appear more numerous as knowledge advanced.

Dr. Brierley read a paper on the mutation of species, in which he appealed for a careful use of the term "mutation," explaining the limited sense in which this term was used in other branches of science. While not denying the possibility of mutation in micro organisms, he considered that no adequate proof of such mutation had yet been adduced, or could be in the present state of our technique and knowledge. Professor Ellis referred to certain remarkable changes in size, shape, fermentation reactions, etc., he had observed in bacteria in prolonged cultivation, but did not claim that these evidenced mutation in the narrower sense defined by Dr. Brierley. Dr. Twort pointed out how unreliable was information derived entirely from morphology, and referred to the difficulty of being certain of "genetic purity." In his reply Dr. Brierley described the manner in which genetic purity could be assured, and declared that there was no biological reason why true mutation should take place. At the adjourned meeting of the Section in the afternoon Professor Ellis read a paper on the intimate structure of the bacterial cell, and described the manner of formation and germination of spores and discussed the presence of nuclei in bacteria. He claimed to have converted non-motile cocci into motile organisms possessing flagellae by frequent subcultivation. A vote of thanks to Dr. Buchanan, President of the Section, was moved by Sir William Leishman and carried with acclamation.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Thursday, July 27th.

The President, in opening the Section, proposed a resolution of congratulation to the Dean of the Faculty in Paris on the occasion of the centenary of the presentation of the thesis by Bayle in which for the first time the view was expressed that the symptoms of paralysis complicating insanity were those of a distinct disease now known as general paralysis of the insane. The resolution was seconded by Sir Frederick Mott and carried unanimously.

Sir James Purves Stewart, in opening the discussion on the treatment of neuro-syphilis, said that neuro-syphilis comprised only those nervous or mental symptoms which were

actually due to the syphilitic virus or its toxin. The present-day classification should be into meningo-vascular syphilis and parenchymatous or degenerative neuro-syphilis and combinations of these. The former included gummata and syphilitic arteritis, and the second those toxic degenerations such as tabes and paralytic dementia. In treatment the physician had to decide on the drug and the channel of its administration. Present-day methods aimed at a combination of salvarsan and mercury. Gummatous lesions responded best to such treatment; in syphilitic arterial lesions the amount of recovery depended on whether thrombosis had occurred, for no amount of treatment would restore an infarcted area. Parenchymatous neuro-syphilis was singularly resistant to treatment, and arrest of the degenerative process was all that could be hoped for. Various supplementary methods of treatment, such as the production of fever, had been employed in association with salvarsan in cases of parenchymatous neuro-syphilis. Query's monkey serum and Dercum's spinal drainage method were referred to. The technique of intrathecal treatment was described and reference made to the various substances employed, and tables showing results of cases treated by intrathecal administration of the patient's salvarsanized serum or of mercurialized horse serum were exhibited. The method was not advisable in paralytic dementia, but in tabes and cerebro-spinal syphilis the results were very encouraging. Some of the clinical results by intracisternal injections in cerebro-spinal syphilis had been striking; it appeared to be the most satisfactory method of dealing with early cases of paralytic dementia. The direct intraspinal administration of arsenical preparations should be discarded.

Dr. Kiunier Wilson (London), in "Observations on the treatment of neuro-syphilis," spoke from the point of view of a clinician. The whole story of the spirochaeta was not known; often there was no sharp line of demarcation between meningo-vascular and parenchymatous neuro-syphilis. Tabes was not purely a parenchymatous degeneration, for there was an active granulomatous infiltration around the posterior nerve roots. Many cases tended to spontaneous arrest and made the result of treatment very difficult to gauge. Of the three methods of treatment—(1) Mercury by the mouth and arsenic intravenously; (2) mercury, and salvarsanized serum intrathecally; (3) mercury, and mercurialized serum intrathecally—the latter on the whole was to be preferred. Successes and failures in tabes were described; slight symptoms and signs at the onset were no guarantee of success in treatment. Treatment had not been greatly improved by the introduction of the arsenical preparation. In some cases the Wassermann reaction could not be influenced by treatment; the aim should be to render the reaction negative, but it was not always possible to do so. Dr. G. K. Adams (Glasgow) discussed the treatment of neuro-syphilis with special reference to changes in the cerebro-spinal fluid. He thought that arsenic given intravenously probably reached the infected focus, though perhaps not in sufficient concentration to be of use; no trypanocidal power was found in the cerebro-spinal fluid afterwards. The symptoms of onset were often overlooked or misinterpreted; if the disease could be recognized in the stage of symptoms before signs developed, much might be hoped for from treatment. Dr. Ernest M. Dunlop (Glasgow) dealt with the bearing of the Wassermann reaction on the diagnosis and the control of treatment in nervous syphilis. He detailed the result of examination of the blood and cerebro-spinal fluid in neuro-syphilis; of the cerebro-spinal fluid in miscellaneous conditions; and of the cerebro-spinal fluid in treated cases of syphilis. In eight cases of tabes out of 107 a positive reaction would have been missed but for the examination of the cerebro-spinal fluid. Dr. Aldren Turner (London) summarized the results of mass treatment of 200 cases of neuro-syphilis from the National Hospital, Queen Square. He divided the cases into: (1) Tabes of long standing with marked signs but a negative Wassermann reaction in blood and cerebro-spinal fluid; this group comprised 10 per cent. of cases. (2) General paralysis and tabes with a positive Wassermann reaction in both blood and cerebro-spinal fluid; 75 per cent. of cases. In this group no material improvement was observed as the result of treatment, and some cases progressed in spite of it. All had intravenous injections of N.A.B. and mercury injections. No intrathecal injections were given. (3) Tabes of short duration in young persons with Wassermann reaction positive in blood and cerebro-spinal fluid, 12 per cent. These improved clinically and serologically. Treatment must be begun

within a few months of the onset. It must be continued for a sufficient time, and it must be repeated at intervals.

Dr. Stanley Barnes remarked that the results of the salvarsan treatment were a little better, but not much better, than those obtained in the old days with mercury alone; in 10 per cent. of all cases the disease tended to die out whether treated or not. The aim should be to find some drug which would precolate more easily. He suggested protein shock in addition to mercury and arsenic injections, in the hope of aiding the precolation of these drugs into the cerebro-spinal fluid.

Sir Frederick Mott doubted if there was much evidence that the arsenical treatment was much better than mercury injection, and therefore prophylactic treatment—the prevention of the entrance of the organism—was of the greatest importance. In 66 per cent. of fatal cases of general paralysis of the insane organisms could be found in the substance of the brain and in the perivascular spaces; they were found especially easily in four cases treated by intrathecal injection. Mercurial treatment was extremely valuable and injection the best way of giving it. He referred to the simple and effective Sicard method which gave small doses on alternate days of N.A.B. hypodermically or intramuscularly in glucose. Professor Browning (Glasgow) considered that no satisfactory experimental evidence had yet been offered of the existence of a neurotropic variety of spirochaete. The problem of therapy in nervous disease was very difficult; all cases attending a venereal clinic should be examined as to their nervous system to determine at what stage neuro-syphilis arises. Dr. David Lees (Edinburgh) spoke from an experience of 3,000 to 4,000 cases of early syphilis in which he had tried all methods of treatment previously mentioned except that by intra-cranial injection. He was not satisfied that any better results were obtained by spinal drainage than by the Sicard method, but in eight of nine cases of tabes in which Query's monkey serum was used intramuscularly very definite improvement followed. Dr. H. J. McBride (London) dealt with the changes in Lange's colloidal gold reaction as a result of treatment, and detailed the routine treatment of neuro-syphilis as employed at the National Hospital, Queen Square. Early optic atrophy should be treated with mercury and iodide.

Friday, July 28th.

In the absence of the President, Professor G. M. Robertson, the chair was occupied by Sir James Purves Stewart. Dr. J. H. Macdonald, in his paper on the element of contrast in the psychic mechanism, said that amongst associative bonds in ideation that due to contrast was very powerful, and had not received the consideration it deserved. From the dawn of consciousness till the end of life man was ever experiencing a contention of elements for and against the expansion and existence of the individual. The importance of contrast was tacitly recognized in the training and upbringing of the child, which to a large extent was based upon the principle of impressing definite ideas of thought and conduct. The capacity to criticize, largely founded upon play of contrasting images, varied greatly in different individuals. Forced inhibitions attendant upon ordinary educational schemes tended to discourage the critical capacity. Notions and doctrines laid down by teachers and parents were apt to be accepted without criticism. Those who wished to encourage the spread of anti-social and revolutionary ideas were fully alive to this fact and sought to impress them upon the child in his early years. The paper was discussed by Dr. Gordon (Bath) and Dr. Helen Boyle (Brighton). Dr. Donald Corio was prevented by illness from reading his paper. In his communication on epilepsy and gunshot wounds of the head, Dr. Aldren Turner said that out of 18,000 cases of gunshot wounds of the head under the Ministry of Pensions, 800, or less than 5 per cent., had developed epilepsy. This was seen in two forms: (1) Following slight trauma without obvious injury to the skull or brain; (2) true traumatic epilepsy following injury to the skull or brain and associated usually with paralytic symptoms. In (1) it was often difficult to say how far the fit might be attributable to the head injury; its importance was due to the number of ex-service men who had received a minor gunshot wound of the head and now stated that they had in consequence become epileptic. Jacksonian epilepsy was rare in comparison with the incidence of ordinary traumatic epilepsy. Traumatic epilepsy following wounds of the brain was attributable in part to the injury, but in greater part to the constitutional disposition of the patient; the local conditions at the seat of injury only in part explained the phenomena.

In the discussion which followed, Dr. Kinnier Wilson said it was very significant that no less than 95 per cent. of head wounds escaped epilepsy; trauma was a grossly overrated factor in the causation of nervous disease. The mechanism of production of a fit was associated with transient vascular changes in the brain; blanching of the cortical surface had been observed to precede a fit. The neuropathic inheritance was of great importance; in many instances similar or dissimilar heredity could be traced. Dr. Wilson related a very striking case of psychogenic epilepsy. Dr. Gordon (Bath) said that all cases of epilepsy in ex-service men in the south-west district of England came into his view. Epilepsy in gunshot wounds did not depend entirely on instability of the nervous system. In dealing with the intelligent and better-class patient much good followed the re-establishment by training of general control. A direct family history of epilepsy was seldom obtained, but 75 per cent. of the epileptics had a neuropathic family history. Dr. Mary Barelay (Edinburgh) held that the fact that of individuals with a wound of the head 95 per cent. did not develop epilepsy was not of much importance apart from knowing what part of the brain was struck and how. Dr. Humphrey (Glasgow) referred to two cases of psychopathic epilepsy. Dr. Macdonald (Govan) inquired as to the relation between traumatic and idiopathic epilepsy; did the mental condition of the patient change in the former as in the latter?

Sir James Purves Stewart suggested that the time had now come to get rid of the term "idiopathic" as applied to epilepsy; its realm was gradually shrinking, and it should be banished. Dr. Aldren Turner, in reply, thought that the term "idiopathic" should not yet be abandoned; there was still a small group of epileptics which could not be satisfactorily classified. The experience of surgeons was eagerly awaited in these cases. Bone-grafting operations might be artistically perfect though therapeutically they left a great deal to be desired. An epileptic should not be considered cured till he had been free from fits for five years.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

Thursday, July 27th.

The proceedings of this Section were opened by a paper by Dr. W. Osborne Greenwood of Harrogate on anaesthetics and analgesics in labour. He pointed out that shock and exhaustion aggravated by pain and fear were the almost necessary accompaniments of every labour. Recent work had shown the profound effect of these factors upon the cells of the master tissues of the brain, liver, and suprarenals. Chloroform and ether given for a prolonged period not only did not give protection from shock, but actually intensified the very condition they were seeking to alleviate; they were actually prone to initiate and continue those cell changes of acidosis, and even disintegration which they were seeking to avert. With scopolamine and morphine they were able to secure that most important consideration, brain rest, while at the same time permitting the essential labour organs to perform their functions perfectly. By those means an ideal labour and a shockless operation could be attained. He then proceeded to enumerate the details of his technique, laying particular emphasis on the testing of the degree of amnesia obtained, and indicating what he regarded as the most important danger signs—analgesia, restlessness, and rapid pulse. These signs were the result of a faulty technique. He laid stress on the importance of regulating the dosage according to the individual patient. With a proper technique he had not met with any bad effects on either mother or child in a long series of cases. In the absence of Dr. Hirschman a paper by him on the standardized dosage method of using scopolamine-morphine during labour was read by Dr. H. G. Taylor, one of the honorary secretaries of the Section. He was followed by Dr. Martin of Bradford, who from the point of view of the general practitioner explained why he had given up employing the scopolamine-morphine method in favour of a method of his own wherein he employed the continuous administration of small doses of chloroform by means of Junker's apparatus, combined with the repeated injection of small doses of infundibulin. In the discussion which followed, the President and Drs. Laphorn Smith, Chalmers, Ruxton, Blair, Russell Andrews, Lackie, Prell, Miller, Thomas, Hendry, and Edon took part. Dr. Greenwood, in a brief reply, said that the question of the employment of twilight sleep should not be regarded simply as one of supply and demand by the patient; he thought the method should be encouraged by the

Dr. T. W. Edon (London) then read a paper on the treatment of eclampsia. He thought the time was now opportune for attempting to secure uniformity in this most important subject, in which up to the present the most elastic views had existed, not only among the general bulk of the profession, but even among teachers themselves, with the result that the most divergent methods of treatment had been employed even in the hospitals. After a brief historical survey of the different modes of treatment given in times past, he quoted the figures which had been recently presented to the British Congress of Obstetrics and Gynaecology at Liverpool. In 1,800 cases treated in hospital in England, Scotland, and Wales there was a mortality of 24 per cent.; in 200 cases treated in hospital in Ireland the mortality was 10 per cent. He laid down a series of propositions: (1) That eclampsia was easier to prevent than to cure; prophylaxis was therefore imperative. (2) Prompt removal to hospital immediately after the first fit should be recognized as absolutely necessary. (3) That a proper classification of cases must be made in order to arrive at the correct indications for treatment. (4) That the minimum degree of obstetrical interference only should ever be carried out—that is, induction if labour were not spontaneous, and low forceps if circumstances demanded this. (5) That the simplest medical methods gave the best results—namely, water only by mouth, and lavage of the stomach and colon, to be repeated if necessary. The paper was discussed by the President, Dr. Campbell, Dr. Douglas, Professor McIlroy, Dr. Laphorn Smith, Dr. Lawrie, Dr. Russell Andrews, Dr. Ballantyne, Dr. Proll, Professor Munro Kerr, Dr. Farquhar Murray, and Dr. Lewis.

Friday, July 28th.

The proceedings were opened by a paper read by Dr. Robert Knox (London) on the treatment of gynaecological conditions by x rays and radium. In dealing with the general question of radiation treatment he said that it would simplify the matter if it were assumed that the potency of the radiation employed was the important point, and that it made very little difference whether the radiation was produced by an x-ray apparatus or a quantity of radium. The essential thing was to be sure that the area treated should get a dose of sufficient intensity to produce the changes necessary for the cure or relief of the condition. The technique of the application and the estimation of dosage were therefore of the utmost importance. Dr. Knox then proceeded to explain the methods employed for arriving at a correct estimation of the dose and the method of application. He stated that the newer methods, particularly that known as the Brämgren method, involved a considerable strain on the patient. He then summarized the contraindications, advantages and disadvantages, and the dangers of x-ray or radium treatment. His own experience had been such that, though some remarkable results had been obtained by radiation, in all cases which were suitable for surgery he strongly recommended it. In the case of fibroids, removal of the tumour was not nearly so rapid by radiation as by operation, while the drain on the system, while not so sudden, might be as severe. He treated these cases in close collaboration with the gynaecologist. An animated discussion then took place, in which the President, Mr. Cecil Rowntree (London), Professor Johnstone (Belfast), Professor Munro Kerr (Glasgow), Dr. Burrows (Manchester), Dr. Farquhar Murray (Newcastle), Professor McIlroy (London), Dr. Chapman (Glasgow), Dr. Gamlen (Newcastle), and Dr. Lochrane (Derby) took part. Dr. Knox, in his reply, dealt with many questions which had been put to him.

A paper was then read by Dr. John Campbell (Belfast) on the treatment of salpingo-oophoritis. At the outset he claimed that no distinction should be drawn between acute salpingitis and acute appendicitis; both might burst and set up general peritonitis. In acute cases, therefore, he urged the necessity of early abdominal operation in preference to expectant treatment. In regard to chronic cases he classified them under two headings: (1) When sterility was the main symptom he thought that expectant treatment should be tried, and referred to the possible advantages of curettage and massage. (2) When pain was the main symptom then he advised that expectant treatment should give place to abdominal operation. As regards drainage after operation on these cases, he confessed that he felt safer in all acute and many chronic cases when he had packed the pelvis with gauze partly ensheathed in thin rubber. He was trying hard to persuade himself to discard drainage; there was

saline and completely closing the parietal wound, but he still thought that in certain cases drainage was absolutely necessary. He advised that a preliminary colostomy should be done on all cases when it was known that an abscess had been discharging into the rectum before the pelvic operation was undertaken. He regarded the use of vaccines as of secondary importance. Dr. Campbell's paper provoked a vigorous discussion, in which the President, Dr. Nigel Stark (Glasgow), Dr. Farquhar Murray (Newcastle), Dr. Camoron (Glasgow), Professor McIlroy (London), Professor Munro Kerr (Glasgow), and Professor Johnston (Belfast) took part. Dr. Archibald Leitch (London) then made a short communication on vaginal involvement in cancer of the cervix.

In closing the proceedings of the Section, the President remarked that the importance of their discussions and the size of their audiences had fully proved the claim of their Section to sit on three days. A vote of thanks to Professor Ewen Maclean for the able manner in which he had discharged the duties of President was proposed by Professor Johnston and carried with acclamation.

SECTION OF PATHOLOGY.

Thursday, July 27th.

A discussion on animal and vegetable pathology in relation to human disease was held on July 27th, with Professor J. H. Teacher in the chair. Professor F. G. Hobday (London) opened the discussion by insisting on the need of close co-operation of pathologists, medical and veterinary, in a united attack on disease common to man and the lower animals. He dwelt particularly on the communicable diseases. Glanders would soon be entirely eliminated from animals in this country, and consequently it could not again be communicable to the human subject. The stamping out of rabies showed what could be done by a collaboration of the two professions. Anthrax, for the occurrence of which amongst animals the importation of animal products was mainly responsible, was largely controlled by the precautions taken by the Ministry of Agriculture, and human cases might be even more satisfactorily diminished. Tuberculosis of milk cattle, responsible for so much of the tuberculosis of children, was unfortunately too rife, and Professor Hobday pleaded for a conjoint effort to get rid of this terrible scourge. Foot-and-mouth disease, cowpox, mange, and ringworm were other instances of animal diseases communicable to man. Professor W. H. Lang, F.R.S. (Manchester), said that it was difficult to make comparisons between diseases in plants and in animals, because the former possessed no anatomical systems comparable to the latter. The connexion, too, between plants and animals was so very remote: they had diverged and were separate as far back as geological evidence went. He demonstrated beautiful sections of ancient plants found in the Old Red Sandstone of Scotland, showing the proliferation of cells around the stomata caused by volcanic gases. The greater part of the paper dealt with the question of plant tumours, and Dr. Lang gave a very able criticism of the view that these crown-gall tumours were similar to animal cancers. The so-called "secondaries," which had been compared to metastases, were not in reality separated from the primary growth: it was only that the increase in length of the stem had separated what formerly had been adjacent tissues.

Sir Clifford Allbutt recalled that at the annual meeting in 1882, and again in his lecture to the Association at its last Glasgow meeting in 1838, he had pointed out the great advantage of the comparative method. No great advance in any department was possible without this method. If it had not been for animal experimentations pathology would have been non-existent. Arguing by analogy had been the bane of science and medicine. Disease was not an entity: it was a deviation of processes, an abnormal series, and not something from without. He thought that the absence of anatomical systems in plants comparable to those of animals was no drawback in the study of comparative pathology: it simplified the analysis of fundamental processes. Professor Gaiger (Glasgow Veterinary College) said that the more they studied animal and human diseases the more they agreed in ultimate detail. A study, too, of diseases peculiar to animals often shed considerable light on similar diseases in man. pure anaerobic cultures that delayed during the war might possibly have been done away with by a study of some anaerobic conditions of the sheep. Mr. W. B. Brierley (Rothamsted), speaking from the botanist's point of view, held that more help would come from a mutual study of pathogenic agents rather than from

investigations of their effects. Analogies between plant and animal diseases must be treated with careful circumspection. But much could be done by workers on both sides in improving technique, in classification of bacteria, in studies on virus diseases, in investigating the rates of dispersal of infective organisms.

Sir William Macewen (President of the British Medical Association) said that he had started that morning to make a tour of the Sections, but as the papers of the Pathological Section had proved so interesting he had remained there the whole time. He emphasized the importance of a combined medical and veterinary campaign against tuberculosis. Dr. Elliot and Mr. Orr briefly dealt with rickets in pigs, and maintained that it was due to deficiency of calcium in the diet, and not to lack of any vitamin. Mr. Gotton, speaking of tuberculosis in animals, stated that 43 per cent. of cattle were affected, but only in a much smaller percentage was the disease communicable. In about 7 per cent. of cows the tuberculosis was generalized. Only 1 in 147 cows had tuberculosis of the udder, and adding to that the number of cases that showed infection of the supramammary lymph glands, there were altogether about 1 per cent. of dangerous cattle. It was an observed fact that cows might excrete tubercle bacilli in their milk without clinical signs of tuberculosis or involvement of the udder.

Friday, July 28th.

Dr. Archibald Leitch occupied the chair on July 28th. Professor Stuart McDonald and Dr. A. F. Bernard Shaw (Newcastle) gave particulars of a unique case of persistent eosinophilia with splenomegaly. The blood condition before and after splenectomy was recorded, together with histological studies of the spleen and lymphatic glands. The authors were inclined to regard the disease as a leukaemia of eosinophiles. Professor J. Shaw Dunn (Birmingham) contributed an important paper on primary chronic interstitial nephritis and arterio-sclerotic kidney. Whilst arterio-sclerosis might cause shrinkage of the renal cortex, it did not produce a condition which resembled true chronic nephritis macroscopically or microscopically. Primary chronic interstitial nephritis or renal cirrhosis was quite distinct from even extreme arterio-sclerotic atrophy, and showed a greater degree of derangement of renal architecture. It was more difficult, however, to differentiate it from secondarily contracted kidney. Dr. E. H. Eastwood (Sheffield), from an examination of appendices removed by operation or obtained in the post-mortem room, found oxyuris as commonly present in the one case as in the other. With regard to the number of eosinophiles present in the wall, which might be taken as a sign of the pathogenic properties of the worm, these were quite independent of the presence of oxyuris, though they bore a definite relation to the duration of the appendicitis. Drs. Bennet, Blacklock, and Browning (Glasgow) gave a convincing account of the value of flavine in severe burn wounds. At no time did a pellicle form over the granulation tissue, as had been asserted, nor was the formation of granulation tissue in any way inhibited. Dr. W. MacAdam (Leeds) read a paper on the decrease of cholesterol of the blood in anaemia. Dr. D. F. Cappel (Glasgow), who had injected certain dyes into the animal body, found that the substances were actively taken up by the wandering connective tissue cells, by the endothelium of lymph sinuses, and the vascular endothelium of certain organs (liver, spleen, and bone marrow), whereas vascular endothelium elsewhere did not attract the dye. Professor M. J. Stewart (Leeds) stated that the healing of gastric and duodenal ulcers was a common event. He suggested that acute and chronic ulcers had an equally good chance of healing. The relation of carcinoma to gastric ulcer, the sequelae of ulcers, and the method of healing were carefully considered.

SECTION OF PUBLIC HEALTH.

Thursday, July 27th.

The first half of the second day's proceedings was occupied by a discussion on the defects of infancy and childhood. Dr. Bruce (S.M.O. Glasgow) described in detail the extent and nature of the defects in local children at the age when they enter school, and several interesting comparisons with other areas were instituted by speakers who followed. Dr. Mary J. Menzies, of the Scottish Board of Health, followed with a description of the different welfare schemes in operation throughout Scotland, which called forth a criticism of the ultimate results of excessive zeal in this direction. The question of industrial fatigue and methods of inquiry were

next dealt with by Dr. McKail (Lecturer on Public Health, St. Mungo's College, Glasgow), followed by a rather technical paper, read by Dr. Paton (Assistant M.O.H. Glasgow) for Dr. J. P. Kinloch (Lecturer on Public Health, Aberdeen), on the constituents of fresh and vitiated air. The paper which gave rise to the liveliest discussion was that of Dr. Wynne (Professor of Public Health, University of Sheffield), who with much causticity, fortunately not unflavoured with wit, criticized the aims and methods of the present-day public health service. Near the close of the session time was found for the reading of an abstract of a somewhat lengthy paper by Dr. Khalil (London School of Tropical Medicine) on sewage disposal in the tropics, with special reference to helminth infections.

Friday, July 28th.

The last day's proceedings opened with a paper by ex-Bailie W. B. Smith (a member of Lord Newton's Committee on Smoke Abatement), which asked the question, "Should we longer tolerate this pollution of the air?" By means of diagrams, maps, and photographs Mr. Smith furnished convincing evidence of the deleterious effect on health of a smoke-laden atmosphere, particularly by the formation of fog, and showed how the prevailing winds cleared certain towns, but smothered others, according to geographical position. Professor Leonard Hill and Dr. T. M. Legge, of the Home Office, entered into the discussion from two opposite standpoints, which left little room for Mr. Smith to reply. The next paper, by Professor Hopo (Liverpool), on the training for the diploma in public health, was read in his absence by one of the secretaries (Dr. J. J. Paterson, M.O.H. Maidenhead), and gave rise to considerable discussion as to whether practice or theory should be accorded the premier place in the preliminary training of a medical officer of health. The second half of this session was devoted to a joint discussion with the Tuberculosis Section upon the administrative requirements of the various types of tuberculosis. Dr. Macgregor (Assistant M.O.H. Glasgow) opened with a paper describing the various methods of treatment applied to a group of some seven hundred ex-servicemen notified in Glasgow as suffering from tuberculosis in one form or other. A number of medical superintendents from well-known sanatoriums took part in the discussion, from which it appeared that, as the President (Dr. A. K. Chalmers, M.O.H. Glasgow) expressed it in summing up, a fork in the path of treatment had been reached. The proceedings then closed with the customary compliments to those who had taken part.

SECTION OF SURGERY.

Thursday, July 27th.

THE programme arranged for the second day's meeting of the Surgical Section, while of great and valued interest both to surgeons and practitioners, did not attract quite such large audiences as were present on the other days. But the scientific value of the session was none the less great. Sir Kennedy Dalziel, one of the vice-presidents, presided. The first subject discussed was the non-traumatic affections of the spleen, and was dealt with in the first instance by a physician—Dr. James Carslaw (Glasgow); then by a pathologist—Dr. E. H. Kettle (London); and the surgical technique was described by the Chairman. Dr. Carslaw, in referring to the lack of knowledge of the function of the spleen, pointed out that one function at least was known—namely, blood destruction, and the cases which seemed to call for splenectomy were those in which these blood-destroying processes were centred entirely, or almost so, in the spleen. Splenomegaly was a feature of many infections, and removal of the spleen was not called for simply because of its enlargement. There were two groups of cases where the disease, probably a toxic agent, seemed to be centred in the spleen: splenic anaemia and acholuric jaundice. Possibly there were other kinds of splenic anaemia, one example of which was Banti's disease. He referred in detail to some of the cases in which splenectomy had been successful. Some of those did not come under the two main categories mentioned. One was a spleen which, after removal, seemed to be tuberculous; whether primary or not he could not say. Another one was pernicious anaemia, though in that disease as a rule splenectomy was not recommended unless there were very definite enlargement of the spleen. There had been only one fatal case in the series and it was difficult to classify it, but he was disposed to place it amongst splenic anaemias, and although the patient's death took place a year afterwards he included

it within the statistics. There was in acholuric jaundice, that many cases of this disease did not require operation.

Dr. Kettle discussed very fully the known physiology and pathology of the spleen. It was a scavenging organ for removal of destroyed or decrepit red cells from the circulation and for liberating haemoglobin and passing it through the liver. Probably the spleen had an important function in combating infective processes by inducing phagocytosis. Some organisms found a resting place in the spleen, and in infections immune substances were found in greater quantity in the organ. Its function had also to do with the digestive system and it was linked up with the ductless glands. Little more was known of the pathology of the spleen than of its physiology. It would seem that increased resistance of the red cells—that is, diminished fragility of the red cells brought about by splenectomy—tended to the disappearance of the disease most suitable for the operation—namely, acholuric jaundice. The position, however, was anomalous, because in many of the cases the fragility of the red cells actually persisted after splenectomy, although the patient was apparently cured. Banti's disease presented a difficult problem because it was divided into three stages by that author; the first of these stages might last twelve years, and he doubted if it were a clinical entity at all. Spleens in Banti's disease examined by him presented very little change; at all events the changes were not commensurate with the clinical manifestations. Before they stereotyped their treatment by splenectomy they should know more about the pathology, though operative treatment was often perfectly justified. The malarial spleen might be removed more often than it was because of the danger of rupture, and because it was a definite focus of infection. The operation was not in many instances an extraordinarily difficult or dangerous one. In children sudden death took place after splenectomy, but at a much later date, when the child had apparently been restored to perfect health; the cause of the sudden death was unknown.

In speaking of the technique of the operation Sir Kennedy Dalziel did not regard the operation as essentially dangerous. The only trouble likely to be met with was haemorrhage. He operated through the incision placed in the middle line supplemented with a transverse incision. He thought that the pedicle should be double-clamped and the spleen removed by cutting between the clamps, so that no blood was allowed to escape from the spleen itself, and the spleen having been removed the vessels caught in the pedicle could be dealt with seriatim. The post-operative leucocytosis found was not greater than that following other major operations. He had had no deaths after removing the spleen.

Mr. A. J. Walton (London) read a paper, illustrated with lantern slides, on the surgery of the pituitary gland. He discussed the anatomy, especially the relation of the arteries in the immediate neighbourhood, pointing out that textbook description was inadequate and generally inaccurate. Pathologically tumours were usually adenomata or cysts; primary atrophy was rare; it was generally a pressure atrophy. Treatment was advocated before general pressure took place. A tumour of the anterior lobe occurring before puberty resulted in gigantism, and after puberty in acromegaly. Another group of cases resulted from diminution in the anterior lobe secretion. Posterior lobe cases were of the type of adiposa dolorosa. He recommended attacking the pituitary by the frontal route, elevating the frontal lobe of the brain. He had operated on seven cases with no special technical difficulty; the mortality was 30 per cent. Three papers on the operative treatment of fractures, from different points of view, were presented by Messrs. G. H. Edington, Archibald Young, and Donald Duff. Mr. Edington was strongly in favour of regarding the plate as a foreign body to be removed between the third and fourth week. Mr. Young showed an excellent series of slides illustrating various methods of dealing with fractures, especially wiring, pinning, or nailing, sometimes using a long nail, sometimes a fine short sprig, plating and screwing. Open operation for fractures was carried out in 32.25 per cent. of the series of cases, which represented the work of the past five years. Of those cases treated by open operation, direct fixation of fragments was carried out in 37.86 per cent. He found that the number of cases in which open operation with fixation was required was increasing on account of the more satisfactory results obtained. Mr. Duff's paper, which was also fully illustrated, was a statement of the work carried out by him in bone operations resulting from the war. He discussed fully the different methods of bridging the gap in the bone; he thought

that the inlay graft gave on the whole the best results. At the close of the session Sir Arbuthnot Lane expressed his gratification at the results of the work of which they had heard that morning.

Friday, July 28th.

The subject chosen for discussion in the third session of the Surgical Section, the treatment of non-malignant affections of the colon, appeared to be the most attractive of all. The audience which assembled under the presidency of Mr. James Berry, a vice-president of the Section, was the largest seen for many years. Whether the subject itself attracted the audience or whether the prospects of a lively debate between such well known and distinguished surgical authorities as Sir W. Arbuthnot Lane, Mr. George Waugh, and Sir Henry Gray, provided attraction or not, is immaterial. In leading, Sir Arbuthnot Lane presented his now well-known theories in an exceedingly attractive and systematized paper. He said there were two great groups of conditions found in the living abdomen—namely, those cases of intestinal stagnation in which reaction took place, and those in which it was absent. The first of these was a group characterized by the formation of bands. The "first and last" kink, a band controlling the lumen and the lower parts of the bowel, was the most important acquired change in the whole body; since it was the primary cause of a vast amount of static trouble in the intestinal tract and elsewhere. Various other localities were affected by the development of bands: immediately above the iliac crests, at the splenic flexure, below the gall bladder, where the band held up and obstructed the transverse colon over the outer aspect of the caecum (Jackson's membrane), and lastly, on the under surface of the terminal mesentery of the small intestine (Lane's ileal band). All these so-called separate bands were evolutionary, and were due to the effort of the organism to meet with abnormal loading up of the bowel because of a distal obstruction. Then came the group characterized by the absence of bands. In this second type of the static colon the mechanical difficulties were the elongated pelvic colon and the obstruction consequent upon it and the inflammation of its mucous lining. The symptoms calling for operation were due to autointoxication, which was the result of infection of the contents of the small intestine. The simplest operative procedure might be to excise the surplus pelvic colon, but in the great majority of cases the best results were obtained by colectomy, or by dividing the ileum and uniting it to the pelvic colon.

Mr. Waugh presented a reasoned statement on the structural variations of the colon, based upon observations made in 518 operations and on a study of *post-mortem* examinations in 110 children under the age of 12 years. He discussed also the symptomatology of the cases presented, and came to the conclusion that undue mobility of the ascending colon was the primo factor in the majority, while others had, in addition, various prolapses affecting the transverse colon, stomach, and right kidney. The operative procedure performed in 210 cases was fixation of the ascending colon to the posterior abdominal wall in what approximated to the normal position. Sir Henry Gray maintained that all these various bands were developmental in origin. Abnormalities in the mobility in the various parts of the colon were due chiefly to the increase or decrease in the fusion of, or in the length of, various folds in the peritoneum formed in connexion with the development of this part of the bowel. Jackson's membrane he regarded as an exceedingly common structure, and it was present to a greater or lesser extent in the majority of patients operated on by him. Jackson's membrane he regarded as developmental, being simply the extension to the right of the omentum. He advocated strongly an extensive paracental incision so that the variations of intra-abdominal structure might be thoroughly investigated and dealt with. Very few cases called for the complete resection of the colon advocated by Lane. This operation was justified only in grave stasis in various parts of the colon and when exploration showed that the colon was an unusually long and hypertrophied one, and affected by adhesions which interfered with its mobility. Mr. Herbert J. Paterson (London) and Mr. A. J. Walton (London) also spoke.

Mr. D. P. D. Wilkie (Edinburgh) read a paper on chronic duodenal ileus, illustrated with lantern slides. The paper was afterwards discussed by Mr. Dingley (Wedsnesbury), Mr. Clay (Newcastle-on-Tyne), and Sir Kennedy Dalziel (Glasgow). The last contribution to the work of the Section was by Mr. H. S. Souttar (London), one of the honorary

secretaries, who described a method of dealing with difficult hernias, the essential feature of which was darning the opening with morerIALIZED silk. Mr. Berry formally closed the Section, expressing the gratification of the officers at its success, and at the good attendance not only by surgeons but by other members of the profession.

SECTION OF DERMATOLOGY.

Thursday, July 27th.

Dr. O'Donovan (London), in opening a discussion on occupational dermatitis, said that in skin diseases the industrial aspect was appreciated more than in any other branch of medicine. The effect of work and stress was more obvious as the cause of skin affection than in any other departments, but it was necessary to investigate the occupation of patients exactly in order to find out what they really did. It was not enough to know that the patient was merely a fireman or a baker without a statement of his exact work. Occupational dermatitis could be grouped according to the nature of the cause. He gave several instances of eruptions caused by rubbing; sometimes the rubbing was aided by syphilis. Dirt was not necessarily a cause of dermatitis. The necessary factor was a cleaning process in which the cleaning fluid came in contact with the skin; the fluid might be water, or acid, or alkali, or benzene, or naphtha, or petrol, etc. Dermatitis was caused by other things also—for example, by vegetable substances. Sugar itch and baker's itch, although well known, he had not often met with. The most chronic cases were those due to formalin and phosphorus. It must always be remembered that the types of industrial dermatitis met with in one's own practice depended on the industries of the neighbourhood. When starting a new industry dangerous to the skin it was essential, though perhaps brutal, to discharge at once all those workers sensitive to the noxious material. Thus a corps of workers immune to trouble would be gradually built up.

Dr. Legge (Chief Medical Inspector to the Home Office), after congratulating the first speaker, said that occupational dermatitis was a clinical rather than an administrative problem. He classified irritants into four kinds: (1) Chemical irritants, such as bichromate, acids, and certain finished dyes—for example, aurantia, which was last used in the German bombs dropped on London; (2) substances which resolve the natural fat in the skin—for example, turpentine, benzene, and its derivatives, the worst being dinirochlorbenzene; (3) macerating substances—for example, water or watery solutions; (4) any process which mechanically injures the continuity of the skin, such as brushing, scratching, and rubbing.

The most interesting problem was that of prevention. He referred to the fetish of the wash-basin, which the medical inspector always asked for in the factory, but washing was bad for eczema when established. He thought the proper preventive treatment was, after work, to rub in a greasy preparation—for example, lanoline, to restore the fat washed out during work. Chromo ulceration was at least thrice as common as tar and pitch dermatitis, but never became carcinomatous. Workmen might find powder useful both on their faces and scrota for preventing the bad effect of tar. Dr. Norman Walker (Edinburgh) said he had been long interested in occupational dermatitis. He desired to say how much had been gained by co-operation with the Home Office, and from intelligent co-operation between the factory doctor and the workman. He gave a good instance of this in the paraffin industry. He thought the idiosyncrasies of various skins to various substances was a factor of great importance. Dr. Gardiner (Edinburgh) said that of all the cases of dermatitis seen by him at least 65 per cent. were due to occupation, but in 14 per cent. the dermatitis was preceded by a definite illness, and 63 per cent. showed a preceding skin abnormality—for example, seborrhoea or hyperidrosis. Slight alteration in the materials used and local injury were important factors. Dr. Lancashire said that the possible sources of irritation were legion. He mentioned novocain as an unusual one, although it had been described previously in America.

The President (Dr. Leslie Roberts, Liverpool) referred to the points mentioned, and desired to draw some general conclusions. He emphasized the importance of examining the entire surface of the body in every patient suffering from dermatitis. The basis of idiosyncrasy seemed to be chemical, often some foreign protein or carbohydrate. Hence in preventive treatment diet might play an important part.

Subsequently Dr. Goodwin Tomkinson (Glasgow) read a short paper on alopecia areata as a family disease. Out of eleven members of a family eight suffered in a varying degree, and seven had strabismus. This group of cases seemed to give support to the theory of the nervous causation of alopecia areata.

DISEASES OF CHILDREN.

Thursday, July 27th.

On July 27th the Section discussed treatment of tuberculosis of the cervical glands. Mr. John Fraser (Edinburgh) said that there existed a wide divergence of opinion as to the correct treatment of tuberculous cervical glands. Nevertheless it should be possible at a meeting such as this to formulate a definite scheme which would guide the practitioner in his advice to a patient. Lymphatic glands might be infected via the blood or via the lymph stream. The latter comprised about 90 per cent. of the cases, but the distinction was an important one, because in the former operation was contraindicated. Clinically it was possible to distinguish between the two groups, because with a blood infection multiple scattered glands were attacked, whereas with a lymph infection the disease remained for a long time confined to one or two adjacent glands. Pathologically cessation occurred in the centre of the gland in blood infections and at the periphery in lymph infections. In the lymphatic variety the primary focus was in the tonsil, nasopharyngeal adenoids, or in carious teeth. Unlike most other forms of tuberculosis, the early stages were not associated with a general infection. There were three pathological types of tuberculous infection in glands—the caseating, the lymphoid, and the fibrous. The caseous variety was the most common. In children under one year the disease generally ran an acute course; with each successive year increasing resistance was developed. Tuberculosis of glands was provokable in 90 per cent. of the cases by sterilization of milk and care in seeing that the child did not come into contact with a case of open tuberculosis. As regards treatment, the speaker did not believe in complete cure by non-operative measures, although the disease might be rendered quiescent. There was no direct specific antibacterial agent for tuberculosis. That being so, he recommended thorough complete removal of the affected glands wherever operation was not definitely contraindicated. The results were eminently satisfactory, because in the lymphatic type of tuberculosis the disease was localized and therefore capable of complete eradication. Under certain conditions, however, operation was strongly contraindicated. These were: irregular, haphazard distribution of the disease, suggesting blood-borne infection; the fibrous type of disease, where incision or curetting had already been performed; and in the first year of life.

The President, Sir Herbert Waterhouse, agreed with nearly everything that had been said. He was especially glad that stress had been laid on the local character of cervical tuberculosis. This meant that the patient was radically cured when the glands were removed. As far as his experience went there was no other cure. The fibroid and lymphatic types of gland were, however, best left alone. As regards the type of bacillus, the human was relatively common in London, although it seemed to be rare in Edinburgh. He wished to enter a protest against treatment by x rays. In the lymphatic type of the disease, when glands were very large, they might do some good, but they rendered subsequent operation extremely difficult. He had never seen a cure follow their use. Mr. Grey Turner (Newcastle) said that he was sorry to be called upon at this early stage of the discussion, because he had found nothing upon which he could differ from previous speakers. He agreed with Mr. Fraser's grouping of cases, and thought that many of the bad results seen twenty years ago might have been obviated had the differentiation between local and general disease been understood. The tubercle bacillus usually gained entrance via the tonsil during the first year of life. It could be found in the tonsil in a large proportion of younger children, but seldom in older cases. He had no objection to operation under one year of age. He gave the after-results in a series of cases which had been operated on five to eighteen years previously. Out of 83 cases 54 were quite well, and 15 had one or two slightly enlarged glands mostly on the side opposite to operation. He recommended removal of the glands at as early a stage as possible.

Mr. Alexander Mitchell (Aberdeen) said that in Aberdeen, in Edinburgh, tuberculosis of cervical glands was particu-

larly common. He thought the milk supply was largely responsible. Unfortunately when milk was sterilized some children did not thrive; it was therefore better to eliminate tuberculosis from cattle. Tuberculosis of glands had diminished since the medical inspection of school children and the removal of diseased tonsils and adenoids. As regards treatment he first dealt with the focus of infection; he then exposed the case to sunlight for two or three weeks; if there was then no improvement he operated. He thought that all cases could be cured by thorough dissection, but that in a few suitable cases curetting was preferable; it was a less serious operation and left a smaller scar. Dr. Thurstfield (London) said that he saw comparatively few cases of tuberculous cervical glands in London, probably because they generally went to the surgeons. The danger of insisting on bovine tuberculosis as a cause was that the very numerous cases due to the human bacillus might be overlooked. The cases of generalized tuberculosis in infants where the primary focus had been in the cervical glands were generally of the human type, and the child had nearly always been in contact with cases of open tuberculosis. Mr. MacLennan (Glasgow) said that the present treatment of milk was a disgrace, and Government interference to put a stop to the use of tuberculous cattle was urgently called for. Cases often began as a mixed infection. There might be tonsillitis, or rhinitis, and tubercle bacilli were introduced along with pyogenic organisms. In Glasgow a very large percentage of cases were due to the bovine bacillus. He did not approve of x-ray treatment, and advocated operation even when an abscess was present. He showed lantern slides illustrating various types of cases. Mr. L. A. Parry (Brighton) said the majority of cases in London were due to the bovine bacillus, and that 10 per cent. of samples of London milk were infected with active tubercle bacilli. Prevention of the disease was extremely important. The supply of non-tuberculous milk was a means to this end. Attention to tonsils and teeth had done much to diminish the incidence of the disease. Operation should be performed as soon as the diagnosis was certain. Dr. Warden (Paris) did not agree with the surgeon's point of view. The profession was greatly divided on the question of operation. Medical treatment had yielded magnificent results, especially from heliotherapy. Tuberculosis of glands of the neck was a symptom of social and economic disease. The public should be enlightened on the subject of tuberculous milk. Dr. Herzfeld (Edinburgh) had followed up a hundred cases of operation in her clinic. There had been only one recurrence. Natural cure might, however, take place. In her series 48 per cent. had recovered without operation, but it was too soon to say if the results were permanent. Dr. Mackenzie (Manchester, China) said that in China there was no bovine tuberculosis because the people did not drink milk. Human tuberculosis was extremely prevalent and many girls suffered from tuberculosis of cervical glands. The boys were less liable because they lived a more open-air life. Dr. Denison Smith said that surgeons often did not see the first stage of the disease, which usually began as a mixed infection. He had obtained good results in 45 per cent. of cases by aspiration of single glands.

Demonstration at the Royal Hospital for Sick Children.

On the afternoon of July 28th the Section of Diseases of Children attended demonstrations at the Royal Hospital for Sick Children. Dr. Alexander Mitchell showed skiagrams of regeneration of bone following resection of the shaft for osteomyelitis. In one case the shaft of the tibia had been completely removed, and the bone had regenerated from the periosteum. There was no shortening and no disability. A similar result had followed resection of the lower half of the femur for the same condition. Mr. Alex. MacLennan showed a series of cases of scoliosis. Some were due to congenital malformations. In the acquired type heredity generally played a part. He discussed the various causes of acquired scoliosis, but had come to the conclusion that the accepted causes did not account for the majority of cases. In his view scoliosis was due to an overgrowth and elongation of the bodies of the vertebra while the posterior parts remained stationary. The only possible way in which the spine could accommodate itself to this state of things was by rotation of the vertebrae, such as occurred in scoliosis. Scoliosis was due to rotation of vertebrae, not to lateral curvature. He explained the treatment by the Abbott method and by operation. He then gave a cinematograph demonstration of the gait in various diseases affecting the hip-joint.

SECTION OF INDUSTRIAL DISEASES AND FORENSIC
MEDICINE.*Thursday, July 27th.*

On July 27th a paper on some factors which make for efficiency and for the social uplifting of industry was read by Sir Thomas Oliver, who pointed out that the subject of "industrial efficiency" could hardly be discussed without its obverse "industrial inefficiency." There could be no industrial efficiency without healthy workpeople. Men must be fit for their job, and those who were fit must be kept fit. There could be no disassociation of employment from home life and the manner in which leisure hours were spent. What public health had accomplished industrial hygiene, its twin sister in the department of preventive medicine, was making an effort to attain. The periodical medical examinations of workers was a matter which called for attention. A medical examination should not be a deterrent but a guide as to the particular kind of work which should be undertaken, and the early years of life were to be considered the vulnerable period. The subject of "group life" insurance was considered in some detail. The paper was discussed by Mr. W. Salisbury Sharpe, who referred to the differences in blood pressure found in various occupations; also by Dr. Scott, Mr. G. E. Orme, and the President.

Dr. James R. Kerr gave a paper on the treatment of industrial accidents. He pointed out that the treatment of an industrial accident had a very close interest for the participants in both its immediate and its remote results. Reference was made to the organization of the factory medical service for dealing with industrial accidents as met with in England and in other countries. While there was good provision for the immediate and immediately subsequent treatment of accidental injuries, there came a stage in the progress of the case when there was no adequate provision for the next essential procedure towards the restoration of the patient to his working capacity, and organized hospital treatment was required. Dr. McVail, Dr. Salisbury Sharpe, and Dr. Coles took part in the subsequent discussion. Dr. John Glaister, jun., read a paper on some new apparatus for the estimation of the working capacity of an upper extremity, and demonstrated the apparatus, which consisted essentially of a box inside which were a number of weights which could be lifted by means of rods passing through the top of the apparatus, the person examined being ignorant of the nature of the weight he was lifting. Dr. Alexander Scott, in a paper on the occupation dermatoses of the paraffin workers of the Scottish shale oil industry, discussed occupation comedones, folliculitis, pustular dermatitis, papular dermatitis, erythema, and epitheliomata, and showed numerous lantern slides and photographs.

SECTION OF PHYSIOLOGY.

Thursday, July 27th.

At the morning session on July 27th Professor D. Noël Paton occupied the chair, and expressed regret for the unavoidable absence of the President of the Section, Professor J. A. MacWilliam, Aberdeen. The discussion on the subject of basal metabolism was opened by Professor E. P. Cathcart, who emphasized the importance of basal metabolism not merely for the physiologist but also for the practitioner. Basal metabolism was the minimum metabolism compatible with life. It might be expressed as oxygen intake or as energy expenditure. There was no such thing as normal basal metabolism; every individual had his own, which showed a remarkable constancy. Basal metabolism, however, was influenced by many factors. There was a diurnal and a seasonal variation. Athletic or sedentary mode of life played a part. But what was of greatest importance from the clinician's point of view was the factor of the patient's condition of nutrition. Clinicians generally saw people in an abnormal state of nutrition. On account of the numerous factors influencing basal metabolism there was a danger of the physician being overwhelmed with an accumulation of utterly worthless data. Dr. J. B. Orr referred to the difficulties of determining basal metabolism, and to the influence of the psychic condition of the subject and the state of the endocrine glands. When the lowest level of metabolism was reached they were dealing really with a pathological condition, intake of nourishment being a normal function of the cell. The conception of basal metabolism was really an abstraction, what was observed was different levels of metabolism.

Professor J. C. Meakins said that the value of observations on basal metabolism depended on the care with which they were made. If proper precautions were not exercised a valuable method for the study of disease might fall into disrepute. He described the conditions of observation in his wards and emphasized the importance of mental apprehension as a factor. Sometimes dummy experiments were necessary to overcome this difficulty. He showed slides demonstrating the result of treatment on basal metabolism in cases of thyroid disease, and of the effect of adrenalin injections on basal metabolism, respiratory quotient, and blood sugar. Dr. G. B. Fleming discussed the influence of age and growth on the basal metabolism of children. The fact must not be overlooked that in such cases growth was going on during the course of the observations. Dr. Leonard Hill spoke of observations on basal metabolism, with special reference to the rate of cooling as observed with the kata-thermometer. Any obstruction to breathing raised the level. One of the greatest benefits of open-air treatment was that it raised the basal metabolism. This was due to the air and not to sunlight. Dr. C. M. Wilson referred to the question of depth of pulmonary ventilation and to subjects in a state of emaciation. He showed slides illustrating the benefit derived in a number of cases of menorrhagia of exposure of the thyroid to x rays. Professor Cathcart, in reply to a request from the Chairman, admitted the difficulties of determination. Basal metabolism was due to the interaction of a large number of factors. Personally he was inclined to associate it with muscle tones.

Mr. G. Hunter contributed a paper on the diazo-reaction of the urine, with particular reference to measles. Various modifications of the diazo reagent were discussed. The importance of using sodium carbonate as alkali and the necessity of adding this to the acid reagent before the solution to be tested were pointed out. The diazo-reaction of a mixed measles urine was shown to be due—to the extent of about 85 per cent. of the colour value—to histidin. Approximately 0.1 gram of pure histidin monohydrochloride was isolated from a litre of urine estimated to contain 0.31 gram. The remaining colour was mainly due to some phenolic substance which was not isolated.

At the afternoon session a combined meeting of the Section and of the Physiological Society was held. The following demonstrations and communications were given: 1. A method of demonstrating arterial blood pressure to large classes. The action of guanidin on the cardiac inhibitory mechanism (Professor D. Noël Paton, Professor D. Burns, and Mr. J. McColl). 2. The influence of oxygen on the pulmonary circulation (Dr. N. Morris). 3. Notes of Thunberg's succinodihydrogenase (Dr. G. M. Wishart). 4. Laevulose in human foetal blood (Mr. A. P. Orr). 5. The influence of calcium on the absorption of phosphorus from the gut (Dr. S. V. Telfer). 6. Postural alterations in the respiration of the rabbit (Professor D. Noël Paton). 7. The effect of sunlight on rickets (Dr. Leonard Hill). 8. The influence of the type of work on mechanical efficiency (Professor E. P. Cathcart, Miss E. M. Bedale, and Mr. G. McCallum). Later in the afternoon Professor Cathcart showed (1) a new type of ergometer designed by Professor Cathcart, Dr. Wishart, and Mr. McColl; (2) the latest type of Benedict-Roth-Collins respiration apparatus for determining basal metabolism.

RADIOLOGY AND ELECTROLOGY.

Thursday, July 27th.

A discussion on the therapeutic value of static electricity was opened by Dr. Howard Humphris (London). He said that there were six chief modalities obtainable for therapeutic purposes: the static bath (also known as the static charge), the wave current, the static induced current, the brush discharge, the static spark, and the high potential vacuum. He described each of these in turn and pointed out their advantages for particular conditions, concluding with the remark that static currents were replaceable by no other form of electricity, and with a competent knowledge of their uses therapeutic effects could be obtained from them which appeared marvellous to anyone using them for the first time. To get these effects consistently, however, it was necessary to have a knowledge of the subject of static electricity and of the nature of the disease to be treated, and to have a static machine of efficient power. Dr. W. F. Somerville (Glasgow) gave an account of high-frequency currents. He brought forward evidence to show that under the influence of these currents definite physiological actions were produced in the

tissues and functions of the body, and that some of these actions were capable of actual demonstration and of precise measurement; also that certain forms of organic diascos were favourably influenced by the application to them of high-frequency currents. He arranged the evidence under three headings: (1) the effects of high-frequency currents on the surface temperature of the body; (2) their action on tissue metabolism, as indicated by qualitative changes in the composition of the urine; (3) their therapeutic efficacy in diseased conditions in which the element of suggestion either did not exist at all or was reduced to a minimum. After a brief discussion in which the President and others took part, a number of papers on x-ray subjects occupied the remainder of the session. The first of these was an account of the Bucky-Potter diaphragm and a lead-glass shield as used for the 7-inch Coolidge tube. This was read by Dr. H. E. Gamlen (Newcastle), who said that the function of the Bucky-Potter diaphragm was to absorb the scattered rays which were generated within the tissues of the body owing to the action of the primary radiation in passing through. The diaphragm prevented the secondary rays from reaching the film or plate, and thus caused better contrast and definition. Dr. C. W. S. Saberton (Marrogate) gave a description, assisted by many slides, of the x-ray appearances in bone disease, with a view to differential diagnosis between simple and malignant cases. His illustrations principally related to osteitis fibrosa, which was liable to be confused with certain other diseases which might simulate it; and in arriving at a diagnosis the clinical history must always be considered in conjunction with the x-ray findings. Dr. James Crockett (Glasgow) read a paper on the differentiation of active from quiescent tuberculosis of the lung. He traced the radiological development of advancing tuberculosis: first a diffuse haziness of the affected area and enlarged trunks radiating from the hilum, these trunks afterwards becoming more accentuated, while budding, rounded or oval in form, appeared on certain branches; the buds afterwards became larger and more numerous, the shadows more dense, and the whole lung at last became dark, save for the light areas significant of cavity formation. Dr. E. W. Reed (Manchester) spoke on the x-ray treatment of diseases of the skin. The conditions contraindicating x-ray treatment he divided into general, such as grave blood diseases, and local, such as acute inflammatory conditions; the prompt application of x rays was indicated when there were indurations and thickenings, itching, chronic infiltrations, lichenification, conditions requiring depilation, and, finally, new growth. The closing paper was read by Dr. Gibson Graham (Glasgow) and recounted the author's twelve years' experience of the x-ray treatment of tinea. Although he had treated children under two years of age, he had never seen any sign of impaired mental function which could be attributed to x rays.

SECTION OF OPHTHALMOLOGY.

Thursday, July 27th.

THE chair was taken on July 27th by Dr. John Rowan, a vice-president of the Section. The subject for discussion, the clinical significance and treatment of heterophoria, was introduced by Mr. A. S. Percival of Newcastle, President of the Section, who said that he would make his introductory remarks brief, so that their distinguished guest, Dr. L. Wobster Fox of Philadelphia, might be able to develop his thesis at greater length. Dr. Fox was given a most enthusiastic welcome, and in his paper he dealt with those aspects of this complicated problem which they in the United States were at this time most actively following. A keen discussion followed, in which there participated Messrs. J. A. Wilson (Glasgow), Charles F. Harford (London), Inglis Pollock (Glasgow), Bishop Harman (London), Gray Clogg (Manchester), Herbert Caiger (Sheffield), Thomas H. Bickerton (Liverpool), J. J. Healy (Llanelli), G. M. Harston (Hong Kong), Stewart Barrie (Glasgow), Lindsay Rea (London), John Rowan (Glasgow). The discussion concluded by replies from Dr. Percival and Dr. Webster Fox. A paper on a case of ophthalmic migraine with unusual symptoms was read by Dr. A. R. Moodie of Dundee; and a paper on the education of partially blind children in myope classes, by Dr. H. Wright Thomson of Glasgow; this was discussed by Mr. Bishop Harman and Dr. John Rowan. Dr. Herbert Caiger of Sheffield communicated a note on conjunctivitis artefacta, which was discussed by Messrs. T. H. Bickerton, Peter Macdonald of York, A. S. Percival, and A. R. Moodie of Dundee. The final paper for the day gave an account of the venereal disease

clinic of the Glasgow Eye Infirmary, and was communicated by Dr. E. J. Primrose; to this there followed remarks by Dr. Ballantyne of Glasgow, Dr. Wilson of Huddersfield, and Dr. John Rowan.

Friday, July 28th.

A clinical meeting was held at the Glasgow Eye Infirmary under the direction of Dr. A. J. Ballantyne, vice-president of the Section. A large series of demonstrations were arranged by officers of the Section besides clinical cases. Dr. Rowan (Glasgow) showed stereoscopic photographs in natural colouring; Dr. A. J. Ballantyne showed drawings of abnormal retinal vessels; Mr. A. S. Percival gave a demonstration of the light sense test; Dr. George Mackay exhibited a retinograph; cases were shown by Messrs. John Rowan, W. Thomson, Garrow, Ballantyne, Leask, Hislop Manson, J. Pollock, Barbour Stewart, E. J. Primrose, and others. Arrangements made for the demonstration of the cases were excellent, and the thanks of the visitors were tendered to officers of the Section and the staff of the hospital.

Reports of Societies.

OXYGEN WANT.

At a meeting of the Edinburgh Medical-Chirurgical Society held on July 5th, with the President, Sir ROBERT PHILLIPS in the chair, Professor J. C. MEAKINS read a paper on oxygen, its causes, signs, and treatment, in which he discussed the importance of oxygen in physiological and pathological conditions. Having reviewed the means whereby the body acquires oxygen from the lungs and the importance of the peculiar character of the dissociation curve of oxyhaemoglobin, he mentioned how the tissues acquire oxygen from the capillary blood. He then summarized the cause of oxygen want and demonstrated the close relation between delirium in pneumonia and oxygen want as determined by the arterial oxygen saturation and cyanosis. Interference with the respiratory function in lobar pneumonia, bronchopneumonia, emphysema, and asthma was discussed in detail, while the protection of dyspnoea and cyanosis in cardiac diseases was interpreted both from the point of view of the oxygen saturation of the arterial blood and also of the minute volume of blood flow through the heart. He demonstrated the causes of orthopnoea and Cheyne-Stokes breathing, and shown how these conditions could be relieved by the administration of oxygen. Professor Meakins considered the influence upon the organism of abnormal composition of the atmospheric conditions in mines and other places. In carbon monoxide poisoning the grave results consequent upon the formation of carbon monoxide haemoglobin in place of oxyhaemoglobin. When the individual was removed from the abnormal environment the carbon monoxide was soon removed from the body, and any after-effects were the result of oxygen want occurring during the period of poisoning.

Dr. WILFRID DAVIES dealt with methods of oxygen treatment. He ascribed failure of oxygen therapy to its exhibition in unsuitable conditions or to faulty technique. The essential consideration was to raise the oxygen percentage, and there the partial pressure of oxygen in the air of the lung alveoli thus giving the oxygen a greater *vis a tergo* in its passage through damaged lung epithelium. Dr. Davies then described the oxygen chamber, the Haldane apparatus, the nasal catheter method, and various emergency methods of oxygen administration.

Surgical Diagnosis of Renal Diseases.

Mr. HENRY WADE read a communication on the choice of methods employed in the surgical diagnosis of renal diseases. In only two types of cases—injury and acute fulminating pyonephrosis—was operative treatment justified without careful preliminary investigation. It was wise in such cases to open the abdominal cavity and examine the other kidney. His routine investigation in the ordinary case comprised clinical examination, including chemical, cytological, and bacteriological examination of the urine, an x-ray photograph of the bladder and both kidneys and ureters, and the use of the cystoscope. Mr. Wade then discussed the indications for ureteral catheterization, pyelography, the use of the ureteral catheter, chromocystoscopy, and renal pelvic lavage. Ureter catheterization was of value in investigating the source

blood or pus in the urine. In intermittent hæmorrhage his custom was to wait till the hæmorrhage was taking place; while one had to remember the possibility of the catheter itself causing a little bleeding, a brisk flow of bright blood should suggest a neoplasm. In pyuria he favoured bilateral catheterization, and with certain precautions this procedure was without danger. Pyelography was useful in confirming the diagnosis of renal tumour because of the characteristic alteration in the shape of the calyces it produced; it was the only sure method of determining the nature of a suspicious shadow, such as that caused by stone, and was helpful in deciding whether or not an abdominal swelling was renal in origin—for example, a displaced kidney. He preferred the x-ray catheter to the wax-tipped bougie in investigating a doubtful shadow in the line of the ureter. The indications for and technique of renal pelvic lavage were also dealt with. To determine the renal function as a whole, blood analysis was of more value than chromocystoscopy, and in the elderly prostatic was an indispensable guide as to when operation could safely be performed.

Reviews:

ARTIFICIAL LIMBS AND AMPUTATION STUMPS.

Mr. MUIRHEAD LITTLE tells us that an artificial foot is referred to by Herodotus as in use as early as 500 B.C., and that at the Royal College of Surgeons there exists an artificial leg found in an Italian tomb at Capua and dating from at least 300 B.C., so that the history of prosthesis is certainly a very ancient one. A sixteenth-century artificial arm is in existence in the Nuremberg Museum, and Ambroise Paré gives descriptions of both arms and legs of considerable complexity, the artificial arms having mechanical hands and fingers working by springs, ratchets, and catches. During the nineteenth century much progress in prosthetic appliances was made, chiefly as the result of attempts to fit men who had been injured in the great wars. Baliff, after the Napoleonic wars, was the first to suggest the use of the shoulder and trunk muscles to work the mechanism of an artificial hand through connecting cords, a method which is now used very extensively in mechanical arms. After the Crimean and Italian campaigns of the French Empire de Beaufort devised several mechanical arms worked in this way, and also invented a very cheap and simple artificial leg. The recent great war has yielded an experience in the fitting of artificial limbs which is unique in history. The total numbers fitted under the auspices of the Ministry of Pensions, excluding members of the Overseas Forces, are:

Lower extremity	29,950 (72.5 per cent.)
Upper extremity	11,350 (27.5 " ")
Total	41,300

Mr. Muirhead Little has probably had a greater opportunity of gaining experience in the fitting of limbs than any other surgeon in this or any other country, and from this experience he has written so concise, lucid and complete a work upon the subject that his book, *Artificial Limbs and Amputation Stumps*,¹ must form a classic for a very long time to come.

It is impossible to do more than select from this work a few items for comment. A chapter on amputation stumps considered from the point of view of the fitting of artificial limbs gives a guide which is essential for every surgeon, for anyone may have to perform an amputation, and it is a confession of failure if the resulting stump is unsuitable for the fitting of an artificial limb. It is to be feared that cineplastic amputations, to which the author devotes the greater part of a chapter, have already become obsolete, the power of the incisors being insufficient and the difficulty of fitting a useful prosthesis almost insuperable.

The British official prostheses, to which a considerable portion of the book is devoted, represent the result of all the accumulated experience of the recent and all past wars, but finally has not yet been reached. Only those types which are strong and useful have survived, and many inefficient appliances have been eliminated. The artificial arms are divided into three groups: those for hard work—"Heavy Workers' Arms," those for light work—"Light Workers' Arms," and those for ornament—"Light Dress Arms." The

heavy workers' arms have, as a rule, detachable forearms and hands, so that tools may be fitted instead. The dress arms are shaped like a natural arm, the forearm and hand not being detachable. The metal parts are of steel or duralumin, the sheaths or shaped parts being of duralumin, leather, or certain mid—the latter a fabric and glue composition, which has been devised in the experimental workshops of the Ministry of Pensions, and which is very light and strong. Mechanical movements of the artificial arm and hand have been extensively developed, and show great ingenuity. The chief stimulus to the production of these has been the Carnes arm, a clever appliance introducing a wonderful imitation of flexion of the elbow, pronation of the forearm, and a mechanical hand grip. Appliances to be used instead of the hand are innumerable; the only apparent difficulty is the selection of those suitable for individual workers. Possibly too many of these have been devised, for, as Mr. Little says, "a visit to a workshop, where a large number of one-armed men are employed, shows that, as a rule, only simple appliances are used." For special work, however, implements of a more elaborate nature may be very useful; as an example may be cited the draughtman's appliance, made by Mr. N. B. Jones for his own use.

A prosthesis for the lower limb is a simpler matter than one for the upper. It is, as a rule, inadvisable to provide for all the normal movements in artificial hip and ankle joints, because the muscles that should control these movements are wanting. The simpler the mechanism of an artificial leg the better, and the British official types of limb may be said to standardize the simplest mechanism which is really strong and reliable. Much controversy has centred around the weight of artificial legs. Mr. Little has always maintained that prostheses, especially for the lower limb, cannot be too light, provided that they are strong enough. He has measured limbs systematically at the hospital at Roehampton, and has come to the additional conclusion that the distribution of the weight is even more important than the total weight. It should be the aim of the designer and manufacturer to raise the centre of gravity as much as possible, so that the distal part of the limb is kept very light. A further point may be put in a patient's own words: "When the socket fits me properly the limb feels no weight at all, but when it is too loose it seems to weigh a ton." Light metal limbs made of duralumin were just coming into use at the beginning of the war. Until comparatively recently the price has been such as to prevent a general issue of limbs of this type, but this difficulty has now been got over, and a footnote in Mr. Little's book tells us that the Ministry of Pensions is now issuing a light metal limb with a wooden socket to those patients who have short thigh stumps and other conditions necessitating a particularly light limb.

Many of the short chapters upon special subjects are of great interest, and will be of immense value to the surgeon in helping him to deal with difficult cases. As examples may be quoted a chapter on appliances for mutilations of the hand, one upon permanent peg-legs, and others on amputation of both the lower extremities, complicated amputations, and the repair of artificial legs. In addition, a short account is given of experimental work by cinematography upon the mechanism of the normal man's gait, and there is a chapter upon re-education of the amputated.

In an appendix full-working details are given. They include the specifications of the limbs which have been standardized by the Ministry of Pensions, an account of the method of using certain mid, and of the method of assembling a light metal limb made by the Ministry of Pensions.

SIXTY-FOUR YEARS A DOCTOR.

THE lean and slipped pantaloons was a picturesque figure enough, but a thought useless, his shrunk shank being controlled by a shrunk mind. It may have been his picturesque-ness that caused him to be enshrined in a poet's phrase, but he must have been dead to talk to. In fact it does not appear that anyone ever did talk to him; which was a pity, because if he had scratched his head hard enough he could probably—even on a very low estimate of his remaining mental capacity—have awakened a few remembrances of the panorama of life which had passed before his eyes. Fortunately in these modern days he has only a small part, for it is no longer indecorous to remain young in spite of advancing years, and it is somewhat of a disgrace to grow old (except in wisdom). By growing old we mean a gradually increasing impermeability to current impressions, a slow withdrawal

¹ *Artificial Limbs and Amputation Stumps*. By E. Muirhead Little. F.R.C.S. London: H. K. Lewis and Co., Ltd. 1922. (Demy 8vo. pp. viii + 319; 267 plates and figures. 18 dols. net.)

into a bi-valvular shell which opens rarely, and may or may not contain a pearl. Such an old mind is content with its own fixed horizon, its own set background of thought; it has forgotten how to press on. To ripen in wisdom is a very different thing, for this involves the continually open mind for ever weighing in judgement the new and the old, so that the new is put on as it proves itself worthy of adoption, and the old is cast off as it becomes effete.

"Different things delight different people. But it is my delight to keep the raling faculty sound without turning away either from any man or from any of the things which happen to man, but looking at and receiving all with welcome eyes, and using everything according to its value." Thus Marcus Aurelius. "There is not a more interesting occupation for the mind of a medical man who has been fifty years in practice than a consideration of the benefits which have resulted to humanity from the discovery of chloroform, aseptic treatment, . . ." Thus Sir Charles Brown, the honoured octogenarian of Preston. That is a far cry from the lean and slippered gentleman, sans everything; and it is entirely in keeping with the wisdom of the philosophic Emperor. But there is this profound difference: whereas Marcus Aurelius enunciated his precepts with obvious self-consciousness, Sir Charles Brown has equally obviously practised his with perfect naturalness.

His book, *Sixty-four Years a Doctor*,² written at the age of 86, reveals the quality of his mind. The book has no conscious art, but it takes the reader right into the presence of the author, as though it were a conversation. It is entirely uncritical, and is simply a record of the things he has seen during his long life. Some of the reminiscences are distinctly quaint:

"Professor A. F. McGill at a meeting of the British Medical Association at Leeds on August 18th, 1889, described how he had already successfully performed the suprapubic operation for prostatectomy, and laid great stress on the fact that the mucous membrane was incised with scissors and the enucleation carried out with the finger. In an adjoining room there was the astounding and unique spectacle of seven or eight old men sitting on a bench with their prostates in bottles on their knees."

Again, with reference to a case of appendicitis (this, in December, 1886):

"I called into consultation the night before the patient died one of the most eminent surgeons in the north of England, and he wished me to inject into the patient's rectum an infusion made according to a prescription of which the following is an exact copy: Common slug tobacco 50 grs., boiling water 15 oz.: infuse for half an hour, cool and strain. Three drams to be used as an enema every half-hour till symptoms of collapse arise."

The author's subsequent comment on the situation thus created is as good as anything in the book. One more quotation must suffice:

"I recall the only occasion on which I saw paracentesis thoracis performed at King's College Hospital. It was in 1858. The fluid was conveyed not through a rubber tube into a basin, but through a piece of chicken's intestine, the distal end of which rested under the surface of water contained in a bucket."

To the layman, also, Sir Charles Brown speaks on many matters of general interest, such as the advances in means of transport; and of many well-known public men he has met, from famous medical men to the late General Booth. Indeed, much of the professional matter would be as intelligible as it would be profoundly interesting to anyone to whom the progress of medical science in the alleviation of suffering means anything.

The book is dedicated very appropriately to Sir Clifford Allbutt; and in a publisher's foreword it is stated that the profits from the sale are to be devoted to the Preston and County Royal Infirmary, with which the author has been associated since its inception. Thus Sir Charles Brown continues his benefactions, not the least of which has been in connexion with the Cambridge Research Hospital, which owes him much.

In September of this year Preston holds its famous Guild after the customary interval of twenty years. Sir Charles Brown must have seen as many of these celebrations as anyone else in the town, and it is to be hoped that Preston will use the occasion to further the object with which this book was written by one of its oldest and most widely honoured citizens.

²*Sixty-four Years a Doctor*. By Sir Robert Charles Brown, M.A., M.B., F.R.C.P., F.R.C.S. London: George Routledge and Sons, Ltd. 1922. (Demy 8vo, pp. 193; 1 portrait. 7s. 6d. cloth; 5s. net, paper.)

"THE ENGLISH SPAW": HARROGATE.

Dr. JAMES RUTHERFORD of Harrogate has laid students of the history of medicine under an obligation by reprinting from the first edition EDMUND DEANE'S *Spadacrene Anglica*, or *The English Spa Fountain*.³ He has increased the debt by inducing Dr. ALEXANDER BUTLER, also of Harrogate, to contribute some biographical notes of Deane, who was an Oxford graduate and a physician in York, and on some others associated with the early days of Harrogate.

Deane's book is little known; very few copies of the first edition, which was published in 1626, seem to be in existence, and the commentators in this edition are able to show that an acquaintance with Deane's treatise would have prevented some errors that have become current about the early history of Harrogate. They establish the fact that the medicinal virtues of a spring on Harrogate moor were first, in modern times at least, recognized, not by Sir William Slingsby, who generally has the credit, but by an older relative of his, also William, who had travelled much and found a resemblance between the water of Spa and that of the Tewelwit well, which was therefore given the name of "the English Spaw." The spring contained iron, as Deane and some other physicians of York were able to demonstrate by adding powder of galls, whereon, to the admiration of Mr. William Stanhope, an ingenious, that is to say curious minded, gentleman who accompanied the party, "the water changed colour, and seemed to blush in behalf of the country, who had amongst them so great a jewel and made no reckoning of it." There is still a Towit well at Harrogate described as a weak carbonate of iron spring.

NOTES ON BOOKS.

Mr. RUSSELL HOWARD'S *The Practice of Surgery*⁴ has now reached its third edition. In it Mr. Howard has endeavoured to set forth the teaching of surgery current at the London Hospital. A work of this kind running to three editions in the course of eight years is one which may be said to have established itself. It is a good average textbook, free from violent prejudices and following the beaten track of established teaching. The illustrations are many, simple, and well chosen, but vary considerably in quality.

Dr. C. W. VALENTINE, Professor of Education in the University of Birmingham, has written a small volume, *Dreams and the Unconscious*,⁵ in which he aims to give an account of the "new psychology" and to indicate what, in his opinion, is fairly well established and what is still speculative theory or hasty generalization. The book is readable and clearly written, but its subtitle, "An Introduction to the Study of Psycho-Analysis," is perhaps somewhat misleading, as the author does not accept the basic principles of Freud's teaching and only deals in a quite general and superficial way with his subject.

³*Spadacrene Anglica, or The English Spa Fountain*. By Edmund Deane, M.D. Oxon. The first work on the waters of Harrogate. Reprinted, with an introduction by James Rutherford, L.R.C.P., Edin., and biographical notes by Alexander Butler, M.B. 1922. GENERAL PRACTITIONERS AND MEDICAL OFFICERS OF HEALTH.

In a presidential address delivered to the conference of medical officers of health held during the congress of the Royal Sanitary Institute at Bournemouth last month Dr. W. J. Howarth, M.O.H. for the City of London, reviewed the relation between medical officers of health and other members of the profession, especially general practitioners. The State, he said, had contracted with one section of medical men to provide treatment to a defined section of the community, and had also established centres for treatment by another section of the profession. The officer of the local authority, the medical officer of health, in establishing these centres, at which payment might or might not be required, acted under instructions, and the scheme evolved might appear to encroach on the sphere of the general practitioner. Such a position might create in the profession discordant sections instead of a united whole. No effort should be spared to establish a

federation of all sections of medicine. To achieve this honest compromises, backed up by unswerving loyalty, must be made. A former member of the Cabinet had rightly insisted that the views of the profession should be expressed by a body representative of all interests.

The general practitioner, Dr. Howarth said, was to be regarded as the backbone of English medicine; there was no doubt that public opinion in medical matters was materially influenced by his support or criticism; his close relationship to individual families and the esteem and admiration generally felt for his self-sacrificing work made him a real representative of medicine in the eyes of the British public. This fact, combined with the growing recognition of the medical ideal that prevention as well as cure is a responsibility of the general practitioner, rendered it essential that the medical officer of health should use every endeavour to secure the goodwill and active co-operation of general practitioners in his public-health proposals. Differences which had arisen in the past had been due generally to misunderstandings. One group had failed accurately to appreciate the objects of the other because means for mutual discussions and criticism had been inadequate or had not been sufficiently used. Medical officers of health were associated in one body which had recently varied its constitution in order to enable all those engaged in the medical work of local authorities to take part in its affairs and management. As a consequence the society would undoubtedly in time to come be even more fully representative of all sections of preventive medicine. Dr. Howarth then continued as follows:

General practitioners have several societies representing their interests, but I believe that the British Medical Association, whilst not only claiming to be representative of all sections of medicine, does actually contain a greater number of members belonging to the group of general medical practitioners than any other society. Here is an organization which some minor change in constitution would probably admirably fit the part of the central body which could provide the necessary means for educating the different sections of medical men in their respective aims and difficulties. Particularly does the organization seem suited for bringing into closer touch general practitioners and medical officers of health.

The difficulties experienced are that the policy of the Association is decided by the representatives in annual council assembled. At such a meeting representatives of sectional interests are not present, unless, of course, as the representatives of areas; as a consequence a section may consider itself aggrieved by an adverse decision, since the decision was arrived at without that full appreciation of the position which would have been the case had direct sectional representatives been able to take part in the debate.

These few points will indicate the lines on which it might be possible for future difficulties to be avoided. The Association may and probably does consider it is rightly entitled to be regarded as the exponent of medical policy. The claim, or the desire, whichever it may be, is to be applauded, provided it can show how sectional interests can receive adequate consideration and ensure a suitable balance of judgement. This proviso is surely not a difficult one; it simply requires an arrangement with the sectional interests to join in its work in respect of matters which are of mutual concern and which require public advocacy and common action. For example, it might arrange for representatives of sections to be directly elected as such to the Representative Body, and even before any final decision as to policy is reached educational methods might be provided for by arranging that a representative of the section should be elected to the Divisions and Branches of the Association, and that corresponding nominees of the Association should have seats on the divisions of the sections concerned. This reciprocal privilege should extend even to the councils of the respective bodies.

A proposal of this kind would surely make for an agreed and uniform policy, and no section would lose its individuality or freedom of action if provision were provided for separate action, though such a contingency ought to be safeguarded by requiring the most careful and deliberate consideration and an exact statement of the difficulties in joint conference before detached action could be possible.

In conclusion, Dr. Howarth said that it was necessary for all engaged in preventive work to practise economy in the expenditure of public money; their proposals must be sound, and must have the support of the stalwarts of the profession—the general practitioners. Proposals on which opinions were divided were more than ever certain of rejection; practitioners and medical officers of health must get into closer touch, and with this object a greater measure of discussion in the privacy of society deliberations must be arranged.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE.

(Continued from page 222.)

The following are some additional notes of the proceedings of the International Congress of the History of Medicine in London, which came to an end on July 22nd.

Anatomy in Edinburgh.

Dr. J. D. COMRIE, in a paper on early anatomical instruction at Edinburgh, said that in the fifteenth century the brethren of the Guild of Surgeons and Barbers maintained an altar, where daily service was held, in the Collegiate Kirk of St. Giles, under the patronage of St. Mungo. In 1505 the guild received a charter of incorporation from the town council; it stipulated that every man before he became a freeman and master of the craft should submit to an examination in the following points: "Thatt he knaw anatomie, nature and complexioun of every member, in manis bodie. And in lykwayes he knaw all the waynis of the samyn thatt he may mak flowbothomea in dew tyme. And als thatt he knaw in quhilk member the signe lies domination for the tyme." A noteworthy concession by the town council, as indicating the beginning of public teaching, was the grant to the guild "that we may have anis in the yeir one condampnit man after he be deid to make anatomie of quhairthrow we may haif experience ilk ane to instruct utheris."

Among the native Edinburgh surgeons mention was made of Anthony Brisset, who treated Queen Mary of Guise (1542); Gilbert Skene, who published a treatise on plague (1568); John Chisholm, who operated on the Regent Earl of Morton for strangulated hernia (1572); and Gilbert Primrose, chirurgion, to James VI and Deacon of the Craft of Chirurgians (1583). A museum was gradually formed in the College of Surgeons, and Monro presented a skeleton (still preserved). Specimens of normal and pathological anatomy gradually accumulated, and in the eighteenth century Barclay commenced his valuable collection of pathological and comparative anatomy, which on his death became the property of the College. In 1831 the University separated the Chair of Surgery from that of Anatomy, thus producing a necessary change in the scope of the anatomy lectures. In 1831 anatomical instruction entered upon the modern epoch in Edinburgh.

Forgotten Teachers at Salerno.

Dr. CAPPARONI related how he had found in a manuscript belonging to the Cathedral of St. Matthew of Salerno many names of medical men unknown to Salvatore de Renzi when he wrote the history of the medical school. The manuscript contained a list, extending from the beginning of the second half of the eleventh century down to the sixteenth century, of the names of members of the brotherhood of St. Michael who died at Salerno. Some names and dates earlier than the eleventh century had been copied into the manuscript from the records of the Benedictines. The new names numbered altogether forty-five, but with regard to fourteen it was uncertain whether they were doctors. He had obtained fresh information with regard to the lives of thirty-six doctors mentioned by de Renzi, and was able to give those of sixty-three followers—English, Scottish, French, and German—who had visited Salerno. Most of the men whose names were given were monks or other clerics. When the practice of medicine outside the cloisters was forbidden, enthusiastic lay medical practitioners increased and guilds of medical men were formed. In his opinion the famous "women of Salerno" were chiefly midwives.

Inoculation for Small-pox.

Dr. TORROMIAN said that those interested in the history of inoculation for small-pox were unanimous in declaring that the practice had been known from time immemorial in China; from that country it was introduced into Persia, Circassia, and Georgia, but they omitted to mention Armenia, situated on the borders of the countries mentioned and in constant relations with them. Armenia had, however, the right to be considered one of the countries which propagated the practice. The method consisted in gathering the scabs of the variolous pustules at the moment of desquamation and preserving them in the pulp of raisins. At first this mixture was swallowed, but later the method of inoculation by incision or rubbing

was practised. He concluded his speech with a tribute to Jenner, whom he calls one of the greatest benefactors of humanity.

Byzantine Cookery.

Professor E. JEANSELMÉ and Dr. L. DECONOMOS contributed a paper on Byzantine food and culinary recipes. The Byzantines, they stated, preferred ground and winged game, and made large use of sea fish and of shell fish. Their culinary methods were complicated. They inherited from the ancient Greeks and the Romans a taste for sauces and highly seasoned dishes, and they drank wines mixed with various ingredients, such as honey, pepper, cummin, cinnamon, and myrrh, and as a people they were far from healthy, and their diet predisposed them to congestion and gout. Great numbers fell victims to these diseases, both in Constantinople and in the principal towns of the Greek empire.

Veterinary Medicine.

Major-General Sir F. SMITH, who contributed a paper on the position of veterinary anatomy in England during the sixteenth, seventeenth, and eighteenth centuries, said that the veterinary knowledge in England during the sixteenth and eighteenth centuries was very small, but considering that anatomy was only beginning to be taught in the fifteenth century, and that no veterinary schools were formed until the eighteenth century, this was not surprising. In the middle of the sixteenth century Thomas Blundell published a book on the study of diseases of horses, but the information it contained was for the most part traditional and often absurd. An Italian, Forraro, of the Neapolitan school of horsemanship, wrote a work on the diseases of horses, which contained two anatomical plates which showed a great lack of knowledge of anatomy. The father of veterinary anatomy was the Italian Ruini, whose anatomical diagrams showed that at least he really studied the subject, and had some conception of the circulation. France and Italy had led in veterinary knowledge, but in this country there appeared to be a national indifference to precise knowledge of the subject.

Professor COLE considered that Carlo Ruini was the father of veterinary science. He was born in Italy in 1530, and became a senator of Bologna. In 1598 he published the first real book on veterinary science and the intricacies of the horse. His diagrams showed that he was the first who really knew anything about the anatomy of the horse. His work went through four editions in Paris, was published in London in 1669, and was often plagiarized. M. LEON MOULE said that Greek and Latin writers had confused several serious diseases of horses with glanders. "Malleus aridus" corresponded to acute glanders, and "malleus humidus" to chronic glanders, but "malleus articularis" was a rheumatic affection, and the "malleus elephantiasis" resembled the elephantiasis of the Arabs. Mr. H. J. SEVILLA said that there was reliable evidence that the Greeks had a very good knowledge of diseases of the horse and of veterinary surgery.

MATERNAL MORTALITY IN DUBLIN AND NEW ZEALAND.

DR. HENRY JELLETT, whose name is honourably bound up with the Dublin school of obstetrics, read a paper this year (1922) at the Annual Conference of the British Medical Association, New Zealand Branch, on the subject of maternal mortality in connexion with child-bearing. His residence in New Zealand enabled him to compare practice in that country and in Dublin. His experience in New Zealand had led him to form certain opinions; one was that the general maternal mortality in New Zealand was somewhat excessive, allowing for all deductions. Others were that the percentage of labours in which the child was delivered artificially was many times greater than was necessary for purely obstetrical reasons, and that the percentage of cases in which there was interference with the physiological mechanism of the third stage of labour was also very high. In his opinion the maternity homes were usually unsuitable in construction and equipment. He noted also that gynaecological and obstetrical operations of every degree of gravity were done by the general practitioner, not merely where expert assistance was lacking but even where it was available.

Dr. Jellet advised each of these opinions in turn and suggested remedies. He had been furnished with figures by

the Board of Health from which it was apparent that the maternal mortality for 1920 was 1 in 154 births, and he had specially scrutinized the worst districts—that is to say, those in which the rate was above the average and those (16 in number) in which it was more than 1 in 100. In the last-named group 5,876 births were attended by 89 deaths (1 in 77). He analysed the causes of death, and found that 74 per cent. of the total were due to four conditions—namely, sepsis, eclampsia, post-partum haemorrhage, and placenta praevia. He instituted the following comparison in regard to these four causes between New Zealand and Dublin (Rotunda) for the past twenty-six years.

Causes.	Mortality Rate.	
	New Zealand (30,761 births).	Rotunda Hospital (44,381 births).
Sepsis	1 in 459	1 in 634
Eclampsia	1 in 831	1 in 1,168
Post-partum haemorrhage ...	1 in 1,051	1 in 7,397
Placenta praevia... ..	1 in 2,796	1 in 7,337

Dr. Jellet was of opinion that the large number of post-partum haemorrhages pointed to the excessive frequency of instrumental deliveries and hurried third stages; the high death rate in eclampsia suggested either a sorer type of disease or unsuitable treatment, probably the latter (Caesarean section done too often); and the mortality from placenta praevia also suggested unsuitable treatment (forced delivery, etc.). His explanation for the high death rate from sepsis was threefold—namely, increased virulence and prevalence of septic organisms (a matter of conjecture), operative midwifery, and unsuitable surroundings. By unnecessary operative midwifery he meant prophylactic ante- or post-partum douching, excessive vaginal examinations, unnecessary forceps applications, and interference with the course of the normal third stage. Private houses adapted to the purposes of a maternity hospital and too small to pay for proper equipment and service constituted unsuitable surroundings. Other causes of the septic mortality were criminal abortion (practically absent in Ireland) and venereal infection. Inmate gynaecology, by producing pelvic infection, caused another kind of mortality—namely, sterility.

Dr. Jellet suggested the following remedies for the diminution of a maternal mortality and a functional mortality which seemed to be excessive in New Zealand. He would alter the relations between the medical attendant and the patient in cases of normal labour. The present relation, as he understood it, was that the medical attendant was expected to be available or even present during a great part of the labour, to shorten the procedure so far as possible, and to be content with an inadequate fee. All cases did not need skilled attendance by medical men all the time; they were better employed in supervising pregnant women and in picking out the cases in which trouble was likely to occur in labour. "There was clearly a large field for ante-natal clinics, provided those who conducted them knew what to look for." In this conclusion it is interesting to note that Dr. Jellet was in agreement with the strong expression of opinion at the recent Glasgow meeting of the British Medical Association (in connexion with the discussions on stillbirths, on eclampsia, and on infantile mortality in connexion with alcoholism), in favour of adequate ante-natal supervision and (when necessary) treatment.

Dr. Jellet advised the erection of midwifery blocks for paying patients in connexion with the large general hospitals, and would abolish all homes which were too small to be run both efficiently and profitably, insisting on the careful examination of all existing homes and hospitals. He would like to see the teaching of obstetrics made far more practical, and urged the provision of post-graduate teaching so that the training of specialists would be possible. Dr. Jellet also expressed the belief that there was a place for obstetrical and gynaecological specialists in large centres, and pleaded for their recognition by the general practitioner. His conclusion is worthy of quotation: "Labour under normal conditions is a physiological process; we cannot interfere with it without making it a pathological process and introducing complications whose possibilities for harm are infinite; therefore the wise and skilful obstetrician avoids interference."

British Medical Journal.

SATURDAY, AUGUST 12TH, 1922.

HOSPITAL POLICY.

THE very long and important discussion on hospital policy during the Annual Representative Meeting of the British Medical Association held lately in Glasgow has been fully reported in the SUPPLEMENT of July 29th (p. 52 and p. 60) and of August 5th (p. 71). The foundations of the debate were the Council's special report on this matter printed in the SUPPLEMENT of February 25th, 1922, and the relevant sections of the Annual and Supplementary Reports of Council published in the SUPPLEMENTS of May 6th and June 24th, 1922. Other stages in the process of collecting professional opinion were the Conferences of hospital staffs called by the British Medical Association in 1920, and again on March 22nd, 1922. We might mention also the discussion on hospital policy from a number of representative points of view in our two first issues of March last. It was claimed for the Council's special report on hospital affairs and the organization of voluntary hospitals that it pieced together a great number of scattered fragments of policy. Its main features were: (1) a general statement on the present-day purpose of the voluntary hospitals, with a definition of the voluntary principle; (2) a statement of the types of patients admissible for hospital benefit, particularly through contributory schemes; and (3) a sketch of the reaction of the new conditions upon the honorary medical staffs. This report was considered by the Divisions of the Association up and down the country, and the task of the Representative Body was to hammer out something that could be put forward as a working policy.

The report and recommendations of the Council were in the main accepted by the requisite two-thirds majority of the Representative Body. But this agreement was not reached without opposition. One important recommendation was taken back for further consideration, and the policy was finally adopted subject to certain definitions and limitations as to the method of its application. The modifications thus introduced are of sufficient moment to require close consideration. In estimating the value and the practical effect of the decisions taken, it is convenient to distinguish three aspects of the special report. In the first place, it may be looked upon as a summary of historical development. As such it met with general approval, and this in itself is no small gain. The facts must be common ground before agreement is reached as to interpretation and action, and it was one of the objects of the report to present a coherent account of widely differing conditions and experience. The reception given to the report in this respect shows that this aim has been attained.

The report next offered an interpretation of facts, whether in a narrower sense by the definition of terms, or in a wider by the analysis of social and economic tendencies, and their probable effect on professional development. Here more definite opposition might have been looked for, and did, in fact, arise, since divergence of experience is necessarily reflected in divergence of sentiment, and interpretation of facts must be more controversial than their record. Even here, apart from verbal amendments aiming at greater accuracy of definition, the report was accepted in its entirety, both as regards definition (notably the definition of the voluntary system and the classification of patients) and as regards the more far-reaching analysis contained in the preamble

and the section on contributory schemes. Here two points of interest emerge: first, that opposition was directed rather to restatement of old policy (as in the case of private patients in voluntary hospitals) than to the enunciation of totally new policy (as in the case of contributory schemes); second, that the field of opposition had been narrowed, as was shown in the discussion on the classification of patients. Both these features of the debate might have been anticipated; for, on the one hand, it is around matters of less recent growth that a definite body of sentiment, based on experience, has arisen; and, on the other, it is only where the old and new systems meet and clash that acute controversy arises. The discussion on the sections dealing with tariff patients showed that even here, by closer definition, it might be possible to keep the controversy within still narrower limits; but it was not altogether clear that such a course would be advantageous at the moment. The final decision to accept the debated section, subject to the interpretation imposed by the withdrawal of paragraphs 33 and 35 (on the formation of staff funds), and the taking back of last year's policy in this respect for reconsideration, if it does not ensure an advance, at least entails no retreat from an established position.

Looking back over the course of the discussions we detect a feeling among the majority that the report offered a plan of action based upon the analysis and interpretation of facts. This plan has been accepted, not, indeed, in its entirety, and not without very definite opposition, but in such a way as to allow of practical development during the coming year. Interest here centres, on the one hand, in the recommendations about the staff fund (paragraphs 33 to 35 of the report), their withdrawal, the various amendments proposed, and the final instruction for further consideration; on the other hand, it rests in the definition and limitation of procedure during the coming year adopted by the Representative Body in approving the report as amended. A critical moment in the long debate was when paragraph 33 of the report was rejected in favour of Dr. Brackenbury's amendment, which excludes from assessment for the staff fund all contributions by or in respect of a patient where these do not exceed the full cost of maintenance and are not derived from State or rate aid. The original report suggested no such limitation, but had proposed that a percentage of all payments made by or on behalf of patients, from whatever source derived, should be passed into a fund which should be at the disposal of the honorary medical staff of the hospital. Now, the Council's recommendation on this point was a logical development of last year's resolution on the same subject—a resolution accepted in its original form by a narrow majority of the Conference of London hospital staffs convened by the Association in 1920, and in the revised form by a far greater majority of the Conference of hospital staffs of England and Wales in March of this year. At first glance, its rejection might seem to mark a retreat from an established position. Closer study, however, shows the decision rather as a recognition of the obstacles in the way of practical application, and the form of the reference back leaves the Council free to search out all paths to a more satisfactory solution of this very difficult problem. Meanwhile, the acceptance of the section on tariff patients in general—adopted with the interpretation needed to bring it into line with the staff fund decision—will, it may be hoped, suffice to meet possible developments.

The final resolution "That the carrying out of the hospital policy of the Association, as now approved, be proceeded with in stages; that during the ensuing session 1922-23, the education of the public in general, hospital governors in particular, and the professional undertakers, and that progress be reported to the

1923," is the measure of the advance made. The hospital policy of the British Medical Association has emerged as a coherent whole, definite enough to cope with the pressing difficulties of the moment, and flexible enough to respond to changing conditions. In the nature of things, its application, like that of certain Acts and Orders, must at first be permissive rather than compulsory, and the "appointed day," as the Chairman of Council has wisely said, is not yet specified.

In the present state of medical opinion the resolutions of a recent conference of the honorary staffs of London hospitals, published during the course of the Glasgow meeting,¹ are of much significance. While neither so comprehensive nor so explicit as the general policy accepted by the Representative Body at Glasgow, they do not, so far as we can see, conflict with it. They show, in the first place, recognition of changing circumstances. Thus the first resolution, excluding from assessment to the staff fund contributions not exceeding the cost of maintenance, is conditioned by the phrase "under present circumstances." Again, the succeeding resolutions mark the acceptance, not merely of the principle of payment of the honorary medical staff where a State-aided or rate-aided contribution is made, but also that of adequate remuneration for treatment at special clinics of patients for whom public authorities undertake responsibility. Whilst the second and third resolutions were not unanimous, they indicate movement along the lines followed in the development of the Association's policy.

THE POET LAUREATE ON THE LANGUAGE OF ANATOMY.

Just what is happening on the pavements of London streets to-day was enacted in the dissecting and examination rooms of Britain some fifteen years ago. "Keep to the right" had grown up to be a rule on London pavements until a self-elected body bounced the public and ordered it to "walk on the left." The result has been and will be confusion until the public decides whether the "right" or the "left" has it. Fifteen years ago English-speaking anatomists had reached a common system of names for the parts and structures of the human body; it was the accepted rule to use words borrowed from Latin and Greek as if they had become English words. In the hospital wards and in examination rooms the teacher and taught understood each other; at least, if they did not, it was not because of any discrepancy in the use of anatomical names. This happy state continued until the ill-starred Basle nomenclature was introduced. Then a confusion broke on the heads of medical students worse in its penalties than that which overtook the builders of Babel. The student could no longer speak in an English way of the "internal cutaneous nerve of the forearm," but must call it by its Basle name, *nervus cutaneus antibrachii medialis*. The new terminology, to be sure, gave the student certain advantages: he could, so far as his terminology was concerned, face examiners in Berlin, Basle, Rome, or New York—but not Paris. Also, when he was duly qualified, and had settled to practice, if he made researches then he could publish them in anatomical terms which could be understood in every country where the Basle nomenclature had come into use. At least, this was the belief which English-speaking friends of the Basle nomenclature urged on its behalf. These advantages, we fear, did not make a very strong appeal to the student.

The attempt to force the Basle nomenclature on the schools of Britain has given rise to controversy and to much learned discussion. It has been left to our Poet Laureate and Dr. Cuthbert Morton to bring the whole matter to a reasonable judgement. The pamphlet just

published,¹ written in the easy clear style which makes one love our mother tongue, gives the English-speaking anatomist guidance to the right way out of the present dilemma. We must give the final opinion of our author in their own words—it is necessary to use "authors," for it is somewhat difficult to tell exactly where the Poet Laureate leaves off and Dr. Morton begins in the page of the pamphlet.

"It will be seen that the import of this disquisition is to condemn the action of those who are moving to introduce a formal Latin international terminology into the British schools of anatomy, on the false notion that it will be of service to international science. It is argued by us that such action is wrong in principle and harmful in practice, and that it cannot secure the advantages claimed for it. We contend that all scientific nomenclature must have its basis in every national language, and that whatever classical or foreign terms are introduced should be as far as possible adapted to the national speech. It is not denied that the work done by the German Committee (B.N.A.) may be of great service. Any combined effort of experts to fix the names of objects that have been variously, confusedly or awkwardly named is a first step towards the simplification and unification of nomenclature; and that is on all hands desired. But those who did this good work never themselves imagined that their attempt was final and in all details satisfactory, and while it should be fully considered and respected, it should be left to the common sense of the workers to take or refuse any suggestion on its own merits. In any case, common sense and convenience will in the end have their own way."

The Poet Laureate has never done medicine a better service than when he added his great influence and experience to the gallant and persistent efforts which Dr. Cuthbert Morton has made to bring order out of the terminological chaos into which British anatomy has been plunged. We should give an altogether misleading impression to our readers if we led them to think this pamphlet is merely for that small section of medical men who are professional anatomists. The authors have explained the principles on which the growth and evolution of the English tongue are based, and what they write of anatomy is applicable to every section of medicine. The "Language of Anatomy" is a pamphlet which every thinking medical man, whether he be reader or writer or both, will study not only with profit but also with pleasure. We sincerely trust it may find its way into every anatomical and clinical laboratory of the United States of America, in Canada, and in Australia, for the case for an idiomatic terminology has never been so justly or so explicitly stated as it has been now by Drs. Bridges and Morton.

ANNUAL MEETING NOTES.

THE PATHOLOGICAL MUSEUM.

THE organization of the Museum Section reflected great credit on Professor J. H. Teacher and Dr. G. Haswell Wilson, who were responsible for the arrangements, and probably never before has one seen at the Annual Meeting such a large and representative collection illustrating all departments of medicine. Out of these exhibits of jar specimens, microscopic slides, photographs, drawings, casts, etc., it is difficult to select those for special mention, as the level of excellence was so high, but we may note some that attracted the most general attention. Of historic interest there were the old anatomical and pathological specimens of William Hunter recently arranged by Professor Bryce, especially those illustrating the anatomy of the joints, lymphatic system, gravid uterus,

¹ S.P.E. Tract No. IX. *The Language of Anatomy*. By William Cuthbert Morton, G.B.E., M.A., M.D. Edited with an introduction by Robert Bridges, M.A., F.R.C.P. Oxford: Clarendon Press, 1922. (Med. 8vo, pp. 27. 2s. 6d. net.)

¹ BRITISH MEDICAL JOURNAL, July 29th, p. 181.

and diseases of bones, now irreplaceable. The request of the organizers for specimens showing the influence of irritants in the production of tumours was well responded to by Dr. Alexander Scott of Broxburn, who showed photographs of the stages of development of epithelioma in paraffin workers under his care, by the lifelike wax models of irritation epitheliomata shown by Dr. Norman Walker, by the microscopic sections of Dr. R. D. Passoy of experimental soot cancer, and particularly by the splendid collection from the London Cancer Hospital Research Institute. In the last case Dr. Archibald Leitch, the director, showed macroscopic and microscopic specimens of his successful experiments in the production of epithelioma, sarcoma, and papilloma by means of shale paraffin and coal tar, metastasizing epithelioma which he and Dr. Kennaway had produced by weak arsenical solutions, as well as various human tumours of theoretical and practical interest—notably a record case of late recurrence of breast cancer (twenty-three years). Mr. Cecil Rowntree, of the same laboratory, exhibited macroscopic and histological preparations of practically all the cases of x-ray cancer known to have occurred in England. To illustrate the discussion on animal and vegetable pathology Professor Gaiger, from the veterinary side, and Messrs. Howells, Robinson, and Walkden from the botanical side, exhibited most interesting specimens of animal and vegetable diseases, especially tumour formations. Specimens of eosinophilia and splenomegaly (Professor S. McDonald and Dr. Bernard Shaw), and chronic interstitial nephritis (Professor J. Shaw Dunn) illustrated two of the important contributions to the last meeting of the Pathological Section. Professor Robert Muir showed what is probably a unique collection of specimens of diseases of the liver, and Dr. G. Haswell Wilson demonstrated embryonic tumours of the kidney and several neuroblastomas. Dermatological, gynaecological, otological, radiological, and surgical specimens were well represented, and special mention should be made of the exhibit from the Research Department of the Glasgow Maternity Hospital, illustrating ante-natal and neo-natal pathology. One could have spent, and many did spend, several hours in the profitable study of the museum specimens.

THE POPULAR LECTURE.

The Popular Lecture was delivered to a very large audience in the Lyric Theatre, Glasgow, on July 28th. Professor J. Graham Kerr, M.A., F.R.S., took for his subject, "The Physician: Naturalist, Teacher, Benefactor," and although there were no lantern views or any other of the usual concomitants of a popular lecture, the interest of the subject-matter and the charm of the lecturer's delivery were such that the audience would gladly have heard more. The lecture is printed in full at page 241. The President of the Association took the chair, and at the close called upon Sir Archibald Garrod to propose a vote of thanks.

Sir Archibald Garrod remarked that the picture of the physician which had been held up that evening would not, he thought, result in any swelling of the head on the part of the medical men who were present. Rather it would humble them, and they would go away thinking that the picture represented them not as they were, but as they would wish to be. In recent times they had learned to clothe science with terrible garments, and had wondered into what new dreadfulness science was going to lead the world. But that was not science, it was the abuse of science. Science herself was not dreadful; it was not even dry. There was in science a great region of fairyland, and the keys which opened the gates to that region were entrusted to a select few. Those who most frequently held the keys were, he thought, the astronomers and the naturalists. Darwin held such a key, and so did Tyndall, and Faraday, and, to come nearer to this generation, Robert Ball. But there were not many, and the key was a very choice possession. Evidently the lecturer of that evening held such a key, and he had opened up some fields much more wonderful than any fields of fancy. Professor Graham Kerr's remarks on the mosquito were most interesting. It was good for people to be taken away for a time from the

strictly human point of view, for, after all, the mosquito or the bacterium could claim that the world was made for it just as much as for a human being. All these forms of life had their own interests, which they did their best to further. The tubercle bacillus had its way to make in the world, and men were always thwarting it, entertaining, apparently, strong prejudices against it, chiefly because it had the unhappy taste to thrive upon the people we could least spare—John Keats or R. L. Stevenson. Professor Graham Kerr had done them all good service by furnishing a new angle from which to view the world of nature and of men.

Sir William MacEwen, before putting the vote of thanks to the meeting, said how greatly interested he had been in the lecturer's allusion to Metchnikoff's work on phagocytosis. The same process was made use of in surgery. Stitches were put in every day, and also certain kinds of drainage tubes, which, after serving their immediate purpose, were taken up by the phagocytes and carried away so far as they were not wanted. The husband of one of his patients complained to him that he was not very comfortable about his wife because more active measures were not taken to heal the operation wound. His reply was, "God does the healing, and we look on." That did not satisfy the gentleman, and he said that surely the stitches must be taken out, or at any rate the drainage tube. Sir William then asked him whether, when he was a boy, he had ever planted things in the soil, and, if so, whether he took them up every day to look at them. As for the stitches, his good lady would "eat them all up," and as for the drainage tube, since this was a chicken-bone drainage tube, the tissues would be trusted to deal with that also. The useful phagocytes would do their work, and at the end of a couple of weeks there would be nothing to be seen. Therefore, phagocytic action was of the greatest importance in surgery in taking away material that was no longer wanted.

Professor Graham Kerr, in responding to the vote of thanks, said that he felt greatly honoured by the presence of the President in the chair, for Sir William MacEwen was the embodiment of the naturalist, the teacher, and the benefactor. Those who had visited Sir William's home in Bute or had gone into his laboratory knew him to be a naturalist through and through. He was also the teacher, keenly interested in the technique of teaching; about his teaching gifts his old students had a great deal to say. Finally, he was an example of the benefactor. "Uneasy lies the head that wears a crown," but those who followed the enthralling story of brain surgery in his Presidential Address must have felt that there were other crowns than material ones, the wearing of which did not make the head uneasy, but rather ministered to its repose.

RECEPTION AND DANCE BY THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The last of the big social functions was held on Friday evening, July 28th, when the President and Fellows of the Royal Faculty held a reception and dance in the McLellan Galleries. This beautiful snito was filled with a gay and happy company of over five hundred, who were received by the President (Dr. W. G. Dun), the Visitor (Dr. W. R. Jack), and the Treasurer (Dr. MacDonald). Dr. Dun welcomed the members of the British Medical Association as the guests of the ancient and Royal Faculty. The arrangements were in the efficient hands of Mr. Walter Hurst, who had provided a short musical programme of songs by Miss King, Dr. T. D. Laird, and Dr. A. N. McLellan, to fill the interval pleasantly.

HOME AMBULANCE SERVICE.

The Joint Council of the British Red Cross Society and Order of St. John has issued a new edition of the list of home ambulance stations, organized by its Home Service Ambulance Committee. The aim is to distribute ambulances on such a scale that wherever illness or accident may occur there shall be a motor ambulance within a convenient distance to carry the patient with a minimum of disturbance and pain to the

but where medical and surgical skill can be most efficiently applied. The scheme is arranged on a county basis, and the 14, which follows this arrangement, shows the places in which ambulances are stationed and the officer in charge at each place. The total number of ambulances in service on March 31st last was 309. The total number of patients treated during the year was 53,743. Not only is the number of persons carried increasing, but also the number carried in each ambulance; the average was approximately 133 in 2021, and 178 in 1921-22. The committee concludes that the service becomes better known to medical men they are turning to it more often for the benefit of their patients. In some instances patients have been moved long distances, for instance from Plymouth to co. Tyrone, by ambulance. In other cases the patient has done the greater part of the journey by rail, but has been carried to the train and from the train by an ambulance. The method adopted in the matter of charges for the use of ambulances varies in accordance with local circumstances, and it is left within the discretion of the county representatives. In many cases the ambulances are maintained by voluntary weekly subscriptions from workmen, and no charge is made for their use. In other instances the costs are defrayed by institutions or by local subscriptions, and generally a charge is made and special allowances granted for necessitous cases. The lower cost of petrol and repairs, and especially the replacement of the heavy ambulances by lighter vehicles, have made possible a very general reduction of charges throughout the country during the year. The accounts received show that, in a well-organized county it is possible to maintain all the ambulances without making any call for subscriptions, or on county funds. The committee has gained much experience in ambulance work and is always ready to advise any organization which is proposing to do work of this nature. At the request of the Queen of Spain the committee undertook last year to supervise the building of four ambulances for the Spanish army; these were delivered at Christmas and gave complete satisfaction. The Government of Fiji also has adopted the plans and specifications in use for the committee's ambulances. Major E. W. Paget, C.B.E., acts as liaison and inspecting officer for the committee. Any medical man who wants an ambulance for the removal of a patient should apply to the officer in charge of the nearest station; if he is not got this information it can be obtained from the county Director. Application for ambulances for the transport of patients in the London area may be made to Mr. F. C. Davies, O.B.E., Secretary of the Home Service Ambulance Committee, 19, Berkeley Street, London, W.1.

A branch of the ambulance work that has made steady progress in the country is that of carrying parties of children from outlying villages to clinics in neighbouring towns. The work, which has been carried out under the direction of the school medical officers, though rather outside the original scope of the committee, is fraught with so much advantage to the health and welfare of the children that the officers in charge of the ambulances have gladly undertaken it.

CHOLECYSTECTOMY OR CHOLECYSTOTOMY.

REMOVAL of the gall bladder has now become the operation of choice, in preference to cholecystotomy and drainage, in the case of the gall bladder, on account of the benefit that results from removal of a faecal infection, of the diminished liability to recurrence of symptoms, to the further formation of calculi, and to primary carcinoma of the gall bladder. By analysis of his own cases Mr. James Sherren¹ has recently shown the superiority of cholecystectomy to cholecystotomy; thus among 184 cases of cholecystectomy carried out in the treatment of calculi confined to the gall bladder and operated upon more than three years ago there were 6 deaths, but no recurrence of symptoms; whereas among 152 cases of cholecystotomy during the same period there were 4 deaths, and among the 148 survivors 34 recurrences. He points out that it is the diseased gall bladder and not its products, whether

infected bile or gall stones, that should be treated, and insists that drainage does not cure chronic cholecystitis. Cholecystectomy should therefore, he considers, be the treatment in all surgical diseases of the gall bladder, as a primary procedure where possible, or, when the risk to life is great, in two stages. The question might be raised whether in a physiological sense removal of the gall bladder is detrimental; in other words, has the gall bladder any functions other than the storage and concentration of bile and the addition to it of mucus? It is possible, as suggested by Rost, that while in the gall bladder the bile acquires some properties valuable in intestinal digestion, which the liver bile does not possess; the dilute state of the liver bile as compared with the gall-bladder bile renders this a reasonable possibility, but there is no proof thereof. From a practical point of view it is to be borne in mind that a diseased gall bladder fails to concentrate the bile or to add mucus to it, and it therefore appears that arguments applicable to a healthy gall bladder do not hold good as regards one in a pathological condition. Mr. Sherren does not attempt to go into those theories with regard to the function of the gall bladder and the changes inimical to the well-being of the patient that may result from its removal, but clinical experience has convinced him that cholecystectomy is safer for the patient, that the risk of recurrence is negligible, and that the loss of the gall bladder in no way interferes with well-being.

THE STUDY OF VENEREAL DISEASES.

THE newly formed Society for the Study of Venereal Diseases held its first general meeting in London on July 31st under the presidency of Dr. David Watson of Glasgow. It was announced that the society has 117 members, but the hope was expressed that this number would shortly be increased, as there are over 200 clinics, with between 300 and 400 clinicians, administrators, and pathologists attached to them. Dr. Watson, who was unanimously elected to the chair on the proposition of Mr. F. S. Kidd, said that whatever objections there might be to the recognition of venereal disease as a special branch of medical practice, facts had got ahead of arguments. It might seem that to group under the heading "venereal" such diseases as syphilis, chancre, and gonorrhoea, which differed so greatly in their manifestations and ultimate effects, was an unscientific method of classifying disease; but they were properly linked together, because the infections were mainly produced by venereal contact, and, what was more important from this point of view, they were amenable to similar methods of prevention and control by health authorities. Whatever might happen in the future, the acceptance of these diseases as a specialty was necessary under present conditions. The decree of the General Medical Council that medical students must receive a course of instruction in venereal diseases established the subject as a specialty. Sir William Macowen, in his Presidential Address to the British Medical Association, had stated with regard to syphilis that now that the Government and the laity had been educated by the medical profession to the fact that syphilis was a preventable germ disease and could be stamped out by known means, this generation, if it did not stop the disease, would commit a crime against posterity. Dr. Watson agreed with this statement, but added that gonorrhoea and chancre should be placed in the same category. Everyone knew, however, that what Sir William Macowen demanded would not result in the present generation from the measures so far taken. The history of modern medicine proved that when a sufficient number of members of the profession became interested in a special branch of medicine it was a great advantage to bring them together for social intercourse, exchange of views and criticisms, and mutual stimulation of research. This was the aim of the new society; it would endeavour to obtain a correct perspective, and while encouraging minute attention to detail would not lose the

¹ J. Sherren, *Brit. Journ. Surg.*, 1922, x, 135-137.

larger view. It would co-ordinate the administrator, the clinician, and the pathologist for the scientific study of the many problems that must be settled before the conquest of venereal disease could be announced. Colonel L. W. Harrison, who added a few words, said that diseases were mostly grouped together for convenience in management, but on account of its etiology and social importance venereal disease was worthy of a category to itself. In spite of current criticism of the venereal clinics he regarded them as a means of stopping the spread of the disease by rendering the greatest possible number of infective persons non-infective. The Presidents of the Royal Colleges of Physicians and of Surgeons, and of the Sections of Dermatology, Urology, and Obstetrics and Gynaecology of the Royal Society of Medicine were elected Vice-Presidents, together with Mr. Frank Kidd and Dr. Wilfrid Fox. Dr. E. R. T. Clarkson was elected honorary secretary, and Dr. Sydney G. Macdonald treasurer. It was agreed to hold six general meetings of the society during the year—on the last Fridays of November, January, March, June, and July, and to hold the annual general meeting next year in London; the suggestion was made that in subsequent years the meeting should be held at the same time and place as the annual meeting of the British Medical Association. A further suggestion to form a local division for Scotland was referred to the Council.

BEER AND LEAD POISONING.

A fortnight ago we stated that we had received information of several cases of lead poisoning among men which it was considered were due to the drinking of beer. We are now able to state that during the last month a considerable number of cases of lead poisoning occurred in certain districts in the County of Middlesex which were traced to the consumption of beer supplied by a particular firm of brewers. A medical practitioner in one of the affected districts promptly recognized that an outbreak of lead poisoning was occurring amongst his patients and at once notified the medical officer of health. The latter found that the outbreak which was fairly widely spread in his district, was limited to persons resorting to certain public-houses in the cellars of which large iron tanks lined internally with white enamel had recently been provided for storing the beer. Samples of beer from these public-houses were taken for analysis and found to contain about one grain of lead per gallon. The beer as it left the brewery was found to be free from lead. It was ascertained that a lead glaze had been used in the preparation of the enamel, and that from this source, owing to the plumbo-solvent properties of its sugars, the beer became contaminated. The use of these tanks was at once discontinued by the brewery company, and risk of further danger from this source was arrested. The persons affected had drunk the beer containing lead for some two or three weeks before the cumulative effect of the poison produced the characteristic signs and symptoms. These included colic, constipation, jaundice, and a blue line on the gums. It is thought probable that cases of lead poisoning ascribed to unknown causes have occurred among persons who resided in other districts and frequented public-houses in which the contaminated beer was sold; but it is possible also that anomalous cases of illness which may have been instances of lead poisoning have been encountered by medical men in or near the districts in which the public-houses in question are situated. During the investigation it was found that another brewery company substituted tanks for barrels in their public-houses, but in this instance the tanks were of earthenware lined with leadless glaze, and no lead was found in samples of beer taken from them. The occurrence is a good illustration of the value of prompt action on the part of practitioners in reporting to the medical officer of health cases of illness which may be due to the contamination or infection of articles of food or drink. It is desirable that the medical officer of health should promptly inform the Ministry of Health of the occurrence of such cases. It sometimes happens that the same causes are operating simultaneously

in widely separate districts, and it is only by co-ordination through the central authority that such occurrences can expeditiously be dealt with.

ROYAL SANITARY INSTITUTE CONGRESS.

THE thirty-third congress of the Royal Sanitary Institute, which was held at Bournemouth from July 24th to 29th, was attended by some 500 persons, including delegates from the British Dominions and Colonies and from many foreign countries, as well as by representatives of Government departments, county and town councils, and other public bodies. The president of the congress was Major-General J. E. B. Seely, M.P., who in his presidential address protested against economies at the expense of the public health, and said that the three very important principles which lay at the basis of the congress were, first, the vital necessity of the health of the people to the maintenance of the British Empire; second, that national health required the organization of all the various agencies; and third, that the health policy of the nation should not be merely the prevention of disease and premature death, but the increase in human capacity and happiness. Great advances had been made in the provision of cleaner towns, better sanitation, good water supplies, food control, drainage and sewerage, but not enough had been done for the education of the people in a healthy way of life. The housing problem could be solved only by steady and persistent work in every district over a number of years. Curtailment in the school medical service had been spoken of in the interests of economy, but he considered that that service was not only saving the lives of hundreds of children, but was laying the foundation for a healthy nation in years to come. Meetings for the reading and discussion of papers were held in five sections: Sanitary Science, Engineering and Architecture, Maternity and Child Welfare including School Hygiene, Personal and Domestic Hygiene, and Industrial Hygiene. In the Section of Sanitary Science a discussion was held on methods of securing continuous treatment of persons infected with venereal diseases, in which papers were read by Dr. J. Johnstone Jervis, Dr. W. E. Facey, Mr. Kenneth Walker, and Dr. Joseph Cates. In the Section of Maternity and Child Welfare including School Hygiene, papers were read by Dr. John Robertson on the regulation of the distribution of milk and food at maternity and child welfare centres, and by Dr. D. C. Kirkhope on certain preventive and curative aspects of the school medical service. Papers were also read on different aspects of maternity welfare by Mr. Aleck W. Bourne, Dr. R. Veitch Clark, and Dr. R. J. Maulo Horne. In addition to the meetings of the sections, a number of conferences were held of sectional representatives, such as sanitary authorities, medical officers of health, engineers and surveyors, veterinary inspectors, sanitary inspectors, and health visitors. The popular lecture, on "The value of clean fresh air," was delivered by Professor Leonard Hill, F.R.S., who said that physiologists could help greatly to point the way to a happy and healthy life, but ignorance and custom enveloped the people, and it was problematical whether our civilization might not stifle itself like older civilizations and die out. The discipline and the laws of health, which included moral restraints, alone could save it.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Work of the Session.

THE adjournment of the parliamentary session on Friday, August 4th, until Tuesday, November 14th, marks the passage of most of the bills and other proposals to which the Government committed itself in the King's Speech on February 7th. Some comparatively small measures are left over, and the text of the Irish Constitution has to await consideration some time hence, for the simple reason that the Irish Provisional Government has not been in a position to translate itself into a parliamentary assembly to frame and pass it on that side. The two outstanding features of the session at Westminster were the enactment of a bill ratifying

the Irish Treaty, and the embodiment in the Finance Act (the corollary of the Budget) of many of the recommendations of the Goddard Committee, with such modifications as appeared necessary to maintain efficiency while making for economy. In that regard it has been recognized that health must be deemed a supreme asset of the nation, in so far as it can be promoted by the State, and so the "cuts" in the Department primarily concerned with it were not so ruthless as was feared at first. Amongst the minor legislative achievements were the passing of the Criminal Law Amendment Act, the Milk and Dairies Amendment Act, and the National Insurance provisions of which were explained in progress was being made. In accordance the Government submitted in the Upper House a series of resolutions giving in outline a scheme for the reform of the House of Lords; but nothing was done in regard to them, nor was anything expected to be done in this connexion at present. It need hardly be added that the statute book, particularly this session, does not convey a correct idea of the value of the contributions by medical members to the debates. They have given valuable knowledge and highly useful suggestions to both Houses in this way, and also by inquiries at question time.

Estimates Committee.—In a general debate on August 1st, on the Report of the Estimates Committee, Sir Frederick Banbury (who was chairman of this independent body) referred to the salary of the chief medical officer of the Board of Education. He receives a salary of £2,520, partly borne on the Education Vote and partly on that of the Ministry of Health, this being an increase of £400 a year upon the salary paid last year. The Estimates Committee did not think that, in the circumstances, the increase was justified. Mr. Fisher, taking this up, said there was no more distinguished public servant than Sir George Newman, no one to whom the health of this country owed a greater debt. Every penny of the salary paid to him was returned to the country over and over again.

Pensions Administration.—A discussion arose on the work of the Ministry of Pensions. Mr. Kennedy said he had evidence that cases passed by medical boards as cases in which the disability was due to or aggravated by war service had been considered by the Ministry at headquarters and the decision of the medical authorities turned down. He quoted a memorandum of the Bristol War Pensions Committee which said that if a man allowed twelve months to elapse before making a claim the invariable conclusion was that the disability had been contracted since discharge, although the man had struggled through this time hoping that his health would improve. Mr. A. Hopkinson, on the other hand, thought that the reason why the Ministry of Pensions was criticized was that it was efficient, doing its duty without fear or favour. Sir A. Warren, speaking from a large knowledge of administrations throughout the country, said that there were scores of cases of men trying to impose themselves upon the funds of the country, but there were thousands of the other kind, and he urged that there should be more consideration. Mr. Duncan Graham said that the views of panel doctors were entitled to as much consideration as those of the ex-service doctors on boards. Major Tryon, replying on behalf of the department, said that fresh claims to pensions were being admitted at the rate of three hundred a week; of that number fifteen to twenty were cases of tuberculosis. Cases of tuberculosis were treated on specially favourable terms, because even when a man was discharged from hospital he got 100 per cent. for six months, although he was very much better, and 50 per cent. for two years, even though he might be well. The policy had been that there should be no economy at the expense of the pensions, but that it should be made and pushed to the utmost on the cost of administration. For the lower estimates of this year there were various reasons, such as children getting beyond the age and widows remarried. About one-fourth of the widows had remarried. The new scheme of administrative areas, replacing the work of the old local committees, was estimated to afford a reduction in expenditure this year of £300,000. When as a result of enormous expenditure on the part of the State in the provision of skilled medical attendance and so on a man got better his pension was reduced, but nothing was said in public about the fact of his being better. Up to a short time ago the net reduction of assessments over the whole range of the medical board was only 5 per cent., and the last figure he had seen was a little less than that. Mr. Adamson, an ex-chairman of the Labour party, spoke of a feeling of dissatisfaction amongst ex-service men in regard to pensions, and quoted certain cases of apparent hardship which, he said, could be multiplied. He suggested that the Government should set up a national appeal board. The Attorney-General pointed out practical difficulties in the way of the establishment of a national appeal board, and the discussion drifted to the problem of finding work for ex-service men. In reply to a question on August 3rd, the Attorney-General said that entitlement and assessment in dealing with appeals were empowered in any case involving a difficult medical or surgical question to send the appeal to be examined by a specialist who should report to the tribunal, or to take the opinion of a specialist upon a case stated to him.

The Manufacture of Morphine.—Replying to Viscountess Astor, on August 2nd, the Home Secretary said that 643,935 oz. of morphine were made in England in 1920. No statistics of the amount used for home consumption were available. The Customs returns showed that 322,484 oz. of morphine and heroin were

exported, but this did not include amounts exported by post or in the form of preparations. The manufacture of morphine could only be carried on under Home Office licence. Viscountess Astor inquired whether 95,000 lb. of special medical opium were sent by the Indian Government to the Secretary of the Revenue and Statistics Department, London. Sir J. Baird said that during the war Indian opium was imported into this country for the manufacture of morphine required by the army. It was sold to the manufacturers in this country. The balance of the stocks were reshipped to India early in 1920, and Indian opium was not at present being used by British morphine manufacturers.

National Health Insurance Expenditure.—At the instance of Mr. T. Thomson, Sir A. Mond, on August 3rd, gave the following particulars of National Health Insurance expenditure for the past two years:

	1920.	1921.
Total expenditure on benefits ...	£18,782,030	£15,611,000
Total cost of administration ...	£4,500,000	£1,827,000

Removal of Ex-Service Men from Asylums.—Mr. Macpherson has stated in a written reply that when a relative insisted on the discharge of a service patient from an asylum against the advice of the medical superintendent the relative was informed that should application be made for readmission of the patient to the asylum (which experience showed usually happened very shortly) the question of reclassifying the man as a service patient, and so entitling him to all the privileges of classification, must be considered afresh. This was a reasonable procedure; it was used with the greatest discretion, and solely in the interests of the patient's treatment and prospects of recovery; it in no way conflicted with the provisions of the Lunacy Act. The arrangement by which service patients were placed on the legal footing of private patients did not remove the Visitors' power of discharge, but it did confer additional powers of discharge by which the responsible relative of a service patient might direct discharge, unless the medical superintendent put in a barring certificate under Section 74 of the Lunacy Act.

Prison Administration.—Sir Thomas Bramston asked, on August 1st, whether, in view of for an inquiry into the Majesty's prisons and would consider the appointment of a thoroughly representative Royal Commission at an early date for this purpose. Mr. Shortt said the matter was under consideration, and he hoped to come to a decision shortly.

Leprosy in India.—Earl Winterton stated, on August 3rd, in answer to Sir C. Yate, that the amended Leprosy Act, passed by the Indian Legislative Council in 1920, empowered local governments to indicate places to be leprosy asylums, and the local areas from which lepers might be sent to such asylums. The treatment of lepers was a transferred subject dealt with in provincial administrations by a minister responsible to the Legislative Council of the Province. The Act was therefore not compulsory. It was in force throughout Bengal and in prescribed areas of Bombay and Burma. Its application was under consideration by the Governments of the United Provinces—Bihar and Orissa and the Central Provinces. It had not been applied in Assam, the Punjab, or the Madras Presidency. The exact number of the lepers segregated under the Act were not available, but 918 were reported to be in asylums in Bengal and 368 in the Bombay Presidency. In Bengal treatment by chaulmoogra oil and its derivatives, in Bihar interventions injunctious of hydrocarbate of sodium and sodium morrhuate had been found satisfactory. In Bihar treatment by antimony was being tried. Recent research tended to show that deficiency in certain essential constituents in diet (vitamins) might be a factor in causing leprosy.

Brief Notes.

Poison gas is manufactured for the War Office now only in such small quantities as are required for research and experiment. The cost was £8,000 a year apart from research and experiment or protection against gas attack.

Mr. Macpherson has stated that subject to overriding considerations of special qualifications and experience—specialist or other—preference is given by the Ministry of Pensions to medical practitioners who served in the war, but by far the greater number of medical men in the employ of the Ministry have had no connexion with army service other than their temporary service in the late war.

In answer to Sir Robert Newman, on August 2nd, Sir A. Mond said that so far as the Board of Control knew, there were fifty-eight county and borough mental hospitals which had no women members on the visiting committee. In these institutions there were approximately 31,000 female patients.

In answer to Mr. Kennedy, on August 2nd, Major Tryon said that during the three months—March, April, and May—the average number of disabled men in receipt of special diet allowances was about 6,700, and in June about 4,200. Of the former 85 per cent. and of the latter 95 per cent. were cases of tuberculosis.

The Minister of Health, in reply to a question, recalled a memorandum issued in 1919, which was to the effect that the practice of spraying halls and places of public resort with a disinfectant fluid was of doubtful utility, and tended only to create a false sense of security.

Sir A. Mond has stated that the total number of cases of scarlet fever reported in the first six months of 1922 was 54,965; in the corresponding period of 1921 it was 56,023. No increase was shown in the more recent returns, the figures remaining fairly constant at about 2,000 weekly. Notification of measles was not compulsory throughout England and Wales, and consequently no reliable figures could be given.

Scotland.

DEATH OF THE INVENTOR OF THE TELEPHONE.

THE death is announced of Dr. Alexander Graham Bell, who made the telephone a practical instrument which could be used both for receiving and transmitting messages. His father and grandfather were both authorities on phonetics and defective speech, and Graham Bell was himself led to his remarkable invention rather through his interest in physiology than through his knowledge of physics or electricity. He had an early link with the medical profession through his mother, who was the daughter of Dr. Samuel Symonds, surgeon in the navy. Dr. Alexander Graham Bell was born in Edinburgh in 1847, and was educated at the Royal High School and the University of Edinburgh; afterwards he went to University College, London, but while still a young man removed with his father to Canada, proceeding later to the United States, where he took the degree of M.D. and was appointed professor of vocal physiology at Boston. It was at Brantford, in Canada, in 1874, that the germ idea of his discovery began to grow, and he linked up his experiments in telegraphy with his study of the movements of the tympanic membrane and bones of the ear during the utterance of sound. He showed a speaking telephone at the Philadelphia Centenary Exhibition in 1876, but it was unnoticed until a chance previous acquaintanceship of Bell with Dom Pedro, Emperor of Brazil, who was visiting the exhibition, brought it to the notice of the judges. In 1877 the University of Heidelberg gave Bell the honorary degree of M.D., but this was probably awarded in recognition of his invention of the photophone and of a telephone probe for detecting bullets in the body rather than for the telephone. In later years he made many other inventions, including the graphophone and a submarine chaser capable of travelling under water at the rate of seventy miles an hour; the laws of flight and the education of the deaf also engaged his attention. In 1906 he received the honorary degree of LL.D. from the University of Edinburgh, in 1918 the Hughes Medal of the Royal Society was conferred upon him, and in 1920, as was recorded in our columns at the time (December 11th, 1920, p. 908), when on a visit to Scotland he was presented with the freedom of his native city.

SCOTTISH BOARD OF HEALTH.

Annual Report.

The three hundred and sixty-five closely printed pages which constitute the Third Annual Report of the Scottish Board of Health (1921) give some idea of its manifold activities. It was not, however, a year of extensions in the work, because the need for economy has dominated all things. At the same time grave unemployment following upon acute trade depression has called for immediate measures, and these have been provided in the Poor Law Emergency Provisions (Scotland) Act and the National Health Insurance (Prolongation Insurance) Act, both of 1921. By means of these Acts provision of food for mothers, infants, and school children has been secured, and large numbers of unemployed have been saved from falling out of insurance. The Board, however, is apprehensive of the effect of the continued industrial distress on the health of the people; and in increased claims for sickness benefit sees signs of lowered vitality. On the other hand, it is encouraged by the steady decline in infant mortality and in deaths from tuberculosis, by the increasing attention which the medical profession generally is devoting to preventive medicine, and by the spread of a knowledge among the people of the elements of personal hygiene.

The report pays a tribute to the services of Dr. John C. McVail, one of the two medical members of the Board. He retired at the end of last year. The Board notes that "when the Scottish Insurance Commissioners were constituted under the National Insurance Act of 1911, Dr. McVail was selected as Medical Commissioner. At that date he had already achieved distinction as a general practitioner, as a county and burgh medical officer of health, and as a medical investigator, teacher, and author. . . . We take this occasion to record our high appreciation not merely of his services as a member of the Board, but also of the distinguished part he has played

in promoting the development of public health administration in Great Britain." It will be fresh in the memory of the profession that Dr. McVail was honoured at the general meeting of the British Medical Association in Glasgow by the presentation of the Stewart Prize.

Scope of the Report.

A glance through the list of subjects dealt with shows the wide ground covered by the report. There are eight large divisions: (1) Public Health; (2) Housing and Town Planning; (3) National Health Insurance; (4) Poor Law; (5) Local Government; (6) Prevention and Relief of Distress; (7) Old Age Pensions and Pensions to Blind Persons; and (8) Miscellaneous. These are followed by valuable appendices (pp. 223-365), containing tables and the like, to which students of vital statistics will go for information, as, for instance, under infectious disease notification (p. 246) and infantile mortality (pp. 248-251). Some surprise entries are found. Thus under "Miscellaneous" there is reference to the religious revival in the North East of Scotland in the following terms, as a result of an investigation by the Board's chief inspector and one of the district medical officers: "The conclusion arrived at by these officers was to the effect that, apart from the attendance at prolonged crowded the more fervent phase of the movement, broke up at a very late hour, the influence of the revival may be a factor in improved mental and physical health; there is overwhelming evidence against the suggestions that it has been in any way responsible for attacks of insanity" (p. 221).

Public Health.

Perhaps the most interesting part of the report to the general practitioner is that dealing with public health, although that on the National Health Insurance will doubtless attract not a few. Public health activities appear under the headings of infectious diseases (from tuberculosis to enteric fever, and including the venereal diseases), sanitary administration (including the question of water supply owing to the long-continued drought, and that of the housing of seasonal workers), maternity and child welfare (now a large and progressive and life-saving business), nursing (dealing with progress under the Nurses' Registration (Scotland) Act of 1919), school health administration (restriction of expenditure), the Highlands and Islands (Medical Service) Fund (with interesting remarks on the attack of whooping-cough in St. Kilda), welfare of the blind (schemes and grants in aid), and inspection and supervision of food. Under tuberculosis the main consideration has been economy, and all projects for new institutional provision have either been abandoned or severely curtailed.

The venereal diseases returns show a small increase in the number of new cases (due rather to the opening of new centres than to any growth in the incidence of the disease), and a larger increase in the number of attendances (a matter for congratulation, as it indicates a growing readiness to continue treatment till medically discharged). A useful table on p. 245 gives a list of institutions approved as venereal diseases treatment centres. Of the total population of Scotland (4,882,288) 4,530,035, or nearly 93 per cent., are resident in areas that now have approved venereal diseases schemes. The good effect of this widespread provision of means of treatment ought soon to be evident. The Board, it is to be noted, is considering the matter of professional secrecy in connexion with these maladies; the question has arisen in England (vide the JOURNAL for June 18th, 1921, p. 904), but not yet in Scotland.

It is noted that encephalitis lethargica is compulsorily notifiable in England but not in Scotland, and the Board adduces the obscure nature of the disease, its low infectivity, and our present ignorance of any specific treatment in explanation of this difference of practice as between the two countries. Inquiry and report, however, by medical officers of health are invited.

Maternity and Child Welfare.

Under the heading of maternity and child welfare there is a distinct note of regret in the Board's comment on the restriction of public expenditure: "Restriction is doubly difficult in a service such as this, which has nowhere reached its full development." The regret is, of course, increased by the consideration of the good results already obtained. The infantile mortality for Scotland in 1921 was 90.3 per 1,000 live births, as against 92 in 1920, which was the . . . till then

¹Third Annual Report of the Scottish Board of Health, 1921. Presented to Parliament by Command of His Majesty. Edinburgh: Published by His Majesty's Stationery Office, 1922. (Cmd. 1697.) Pp. 365. Price 1s. net.

recorded. Notice should be taken of the significant remark, "This figure excludes, of course, stillbirths and all ante-natal deaths"; it is good, therefore, in itself, but it is incomplete. It is to be hoped that through notification the stillbirths rate will soon be known and published. In the meantime the earlier ante-natal deaths can hardly be counted, and matters are scarcely ripe for an abortion rate. It is, however, a matter for the consideration of the Board whether the deaths in the first month of life should not be extracted and presented in the form of a new and separate rate. In the tables the deaths in the first week are stated, and those after the first week and under one month, but a neo-natal or primi-menstrual rate put prominently forward under its own distinctive name would be of great value in estimating the health conditions in town and country. The neo-natal rate would probably be found to be the most sensitive index of general well-being in a community, especially if it were accompanied by a stillbirths rate.

The Board is concerned regarding the preventive treatment of ophthalmia neonatorum, and has issued a circular (Appendix iv, p. 231) regarding the treatment of the infant's eyes at birth with a solution of silver nitrate (1 per cent.). The Board ought not to forget that the true preventive treatment of this disease lies with the curing of the expectant mother's gonorrhoea.

Conclusion.

The report forms a remarkable record of health activities; and whilst the reader is led rather abruptly from the largest to the most trifling matters, his interest is never allowed to flag, and that is high praise of a more or less statistical work. The question of the Drug Fund under Medical Benefit is a big matter, whilst the proposed cinematographic installation in a Poor Law hospital (fireproof chamber needed for entertainments to the children) is a very small one; but each is dealt with intelligently and no doubt wisely by the Board. The fireproof chamber, it may be noted, was not forthcoming. The report, as a whole, is one upon which the Board may justly congratulate itself and receive congratulations.

England and Wales.

METHODS OF HOSPITAL ACCOUNTING.

THE Voluntary Hospitals Commission has under consideration the form of account to be recommended to local hospital committees in order to secure uniformity and so facilitate comparison of the real cost of maintenance of hospitals. In a pamphlet recently issued the Commission makes two recommendations: (1) Hospitals which can do so are advised to use the "Revised Uniform System" and no other though it have a similar name; (2) cottage hospitals and others small hospitals unable to keep the Revised Uniform System of accounts are urged to keep the "Simple Cash Account" which is shown in the appendix of the pamphlet now issued. It is impossible, states the Commission, to lay down any general rule as to the line of demarcation between the two classes of hospitals. The mere number of beds is not an adequate test of the ability to keep the Revised Uniform System, since some hospitals with a comparatively small number of beds and a large out-patient department may have a larger clerical staff than a general hospital with the same number of beds. It is suggested, however, that committees should not agree to the adoption of the Simple Cash Account in the case of hospitals with over fifty beds, except in exceptional circumstances.

HOSPITALS OF LONDON COMBINED APPEAL.

A special meeting of the President and General Council of King Edward's Hospital Fund for London was held at the House of Lords on August 1st, to authorize an interim distribution on account of the proceeds of the Hospitals of London Combined Appeal. Mr. M. C. Norman, Governor of the Bank of England, presided. Sir Alan Anderson (chairman of the Revenue Committee of King Edward's Hospital Fund for London and chairman of the Organizing Committee of the Hospitals Combined Appeal) said that at the end of the first stage of the appeal the amount in hand closely approached what was expected. Before the appeal was started in April Mr. Strappell-Smith hoped to get in £300,000 by July 31st. Including the money advised and intimated he now expected slightly to exceed £300,000; of this £271,000 was actually in hand, and large sums were coming in every day. On the

other side of the account there were heavy expenses, amounting to date to about £30,000; this, however, was less than the Appeal Committee had been warned to expect. The free grant of space on hoardings had made it possible to reach the public by poster at about one-fifth the ordinary cost of such advertisement. The sum collected could not have been raised without the special advantages which the King's Fund had, and which no other appeal could have had. The support given to the appeal by the Royal Family was of immense value. The medical students also had been of enormous use, and had put life into everything they touched. The Hospital Savings Association, of which Lord Hambleden was chairman, was intended to bring regular weekly contributions from wage-earners to the hospitals. It was really to give the hospitals time to get those regular weekly contributions organized that the combined appeal was started. Sir Alan Anderson, in conclusion, mentioned that the temporary Government grant to hospitals had been subject to a fundamental condition that an equal sum should be raised from the public. The appeal had already succeeded in raising as much "new money" as the maximum amount of Government money at present available for London hospitals, and the newspapers and committees had been informed, accordingly, that the Government could no longer give "pound for pound" to balance new money contributed by the public. The Management Committee recommended that the King's Fund should pay to the co-operating hospitals cheques on account on some date between August 1st and August 15th, amounting in all to £150,000; and that a further payment on account should be made to each hospital after the holidays as soon as sufficient further information became available.

Correspondence.

THE TEACHING OF PSYCHOTHERAPY.

SIR,—Will you permit the intrusion into the discussion on psycho-analysis of one who is neither a neurologist nor a psycho-analyst, but who has in the course of desultory reading followed to a certain extent the literature dealing with the new method of interpreting dreams?

According to Freud (*Interpretation of Dreams* (translation), p. 483) "the interpretation of dreams is the *via regia* to a knowledge of the unconscious in the psychic life." It will be admitted, I think, that the existence of an unconscious mind in the sense that this is a storehouse of thoughts, is a *primo* factor in the psycho-analyst's position. Let us then for a moment examine the evidence.

In considering the process of thinking we must depend upon scientific analogy. Is not the most probable hypothesis that some stimulus sets up changes (chemical, and perhaps electrical) in a given cerebral area, and that as associated areas become involved other thoughts are added, and that after the process is over these parts return to rest? This would explain conscious thinking, but leaves no place for the unconscious as the term is used by psycho-analysts. I have just read *The Psychology of the Unconscious*, by Jung, and found it a very interesting and learned study of myths and folklore, but as for the "unconscious" it is simply assumed. Psycho-analysts should therefore give us a statement compatible with physiology as to what they conceive to be the biological process involved. With regard to the interpretation of dreams, I presume that psycho-analysts still follow Freud. Now, this author seems to contradict himself with regard to a point of great importance. In his large work (*loc. cit.* p. 454) we read: "We must therefore admit that the dream invariably awakes us"; while in the *Introduction to Psycho-analysis* (translation), p. 76, he writes: "We do not wake up out of all dreams."

It would unduly lengthen this letter to give details as to the symbology employed in interpreting, but it really seems that psycho-analysts refuse to admit an innocent dream—long objects mean the male organ, short ones generally the female; rhythmic movements like riding and going upstairs signify coitus, and so it goes on. To show that this is not a travesty I may again quote Freud (p. 241): "We have already asserted elsewhere that dreams which are conspicuously innocent invariably embody coarse erotic wishes."

Much more might be adduced to show the trend of thought adopted by psycho-analysts, but I shall conclude by asking another question. As obviously their elaborate code of symbols cannot be known to their patients; who

suggests the meanings to be utilized in interpretation? It may be a good thing to have worries talked over, but is it desirable to suggest sexual problems? It may be replied that these are the difficulties of one not conversant with the "new science," but most of us dream dreams on occasion and are able to judge for ourselves how far this unpleasant element enters into them.—I am, etc.,

Harrogate, Aug. 6th.

P. McBRIDE.

AMAS OR ALASTRIM.

SIR,—The letter from my old friend Dr. de Korté in your issue of July 8th (p. 65) provokes me to break a lance with him. My own opinion, based on experience in Central Africa, has led me to the belief that the names "amas" and "alastrim" are merely synonyms for small-pox in mild form, but I am, of course, open to conviction.

Dr. de Korté states that "amas, so called by the natives of South Africa, has been endemic for centuries." Surely this is rather a sweeping assertion. If we except the Cape peninsula and a comparatively small area round it, our knowledge of South Africa and the kaffirs belong almost entirely to the last century. Moreover, an expert bacteriologist like Dr. de Korté would not, as a rule, attach much weight to diagnosis and nomenclature belonging to the pre-scientific period. Dr. Livingstone, an early and accurate observer, nowhere, as far as I recollect, mentions anything but small-pox.

A footnote to history may shed some light on the subject. In 1881, or thereabouts, small-pox broke out in Kimberley, which at that time depended upon bullock wagon transport for all its supplies, fuel as well as food. As a result rates soon rose to a prohibitive figure and lack of fuel threatened to bring the mines to a standstill, and probably, what was regarded by many as equally important, the liquor supply showed signs of shortage. The authorities were in despair, but eventually, backed presumably by some medical opinion, they gave currency to the statement that the disease had been recognized as "Kaffir pox," which "did not attack Europeans." The scare subsided, the epidemic went on its way, and things resumed their normal course, but there were left behind the germs of a myth now grown to such dimensions as to have acquired a high-sounding name. I would ask Dr. de Korté if he can name any medical authority who had recognized "amas" as a separate disease before 1880.

That Europeans rarely contract small-pox from natives is true, for the simple reason that they are generally protected by vaccination. When not so protected they may become infected in virulent form from very mild cases of the disease, such as would, I presume, be called "alastrim." For the truth of this I can vouch from experience.—I am, etc.,

London, W., July 11th.

R. U. MOFFAT, M.D.

* * We have received from Mr. H. A. Moffat, F.R.C.S., of Cape Town, a letter dated June 27th giving information very similar to that contained in the third paragraph of the letter printed above. He says that it was announced that "the disease was not small-pox but the comparatively harmless thing labelled 'amas.' The scare subsided and the price of wood fell. Vaccination had been carried out and the cases isolated, and the epidemic also subsided."

CALCIUM DEFICIENCY AND COD-LIVER OIL.

SIR,—The investigations of Grove and Vines on calcium deficiencies and their treatment by parathyroid, the results of which were published in your issue of May 20th, 1922, may on further pursuit afford a rational basis for the treatment of some diseases at present carried out empirically with greater or less success.

One of these diseases is phthisis, and it is noteworthy that the treatment proved by long experience to be most efficacious in it is a combination of fresh air, sunlight, milk, eggs, and cod-liver oil, and it is significant that the recent work on rickets¹ has shown that cod-liver oil and sunlight exert a markedly favourable influence on the calcium metabolism of the body, which will no doubt on investigation prove to be definitely associated with an increase of ionic calcium in the serum, and it is well known that milk and eggs are foods particularly rich in organic calcium.

It is also highly significant that in the only case of tuberculosis recorded in their paper, Grove and Vines found a

marked and intractable deficiency of ionic calcium in the serum, and that it was only on the restoration of the calcium content of the serum to normal that the process of healing commenced.

It is, moreover, stated by Fisac that few or none of those employed in lime works, and who therefore habitually inhale, and presumably absorb, large quantities of lime dust, ever contract phthisis, even though living in squalid dwellings and underfed, and this is corroborated in a striking manner by Tveddell.²

Pathology also teaches us that the complete healing of tuberculous lesions in the lungs is associated with the deposition in them of calcium salts. *Per contra*, pregnancy and lactation, which are known to impose a severe drain on the calcium resources of the body,³ are recognized to be particularly fatal to those affected with pulmonary tuberculosis.

I would therefore suggest that the value of cod-liver oil, milk, eggs, and sunlight, in phthisis is in all probability due to their favourable influence on the calcium metabolism of the body, and that their effect in this respect may be found to be heightened by the simultaneous administration of parathyroid or other calcium-conserving endocrine substance. Cod-liver oil might advantageously be administered during pregnancy and lactation, and in other conditions associated with great calcium katabolism, where the ionic calcium of the serum is on investigation found to be persistently diminished.—I am, etc.,

Asansol, Bengal, June 22nd.

JOHN W. TONE.

THE TREATMENT OF TUBERCULOSIS WITH COLLOID CALCIUM.

SIR,—Since publishing my article in your JOURNAL (January 14th, 1922, p. 53) I have had a good many inquiries about the best methods of administering colloidal calcium; and as I have been giving it largely since that time I think it would be well to add a little to the information given in that paper. I may say that since using this drug the running of the sanatorium has been much easier than formerly owing to the beneficial effects produced. In addition to giving injections I have for some months been giving it by the mouth; the preparation I have used was the same as that used for injections, except that it contained 3 grains of calcium lactate to the dose, the dose used being 1 drachm, given one, two, or three times a day. This method has been peculiarly successful in reducing sputum and getting rid of tubercle bacilli from the sputum. I have reason for supposing that given by this method the action is rather different than when injected; the dose is certainly much greater. It seldom produces any untoward symptoms, but it is well to keep a chart of the temperature whilst it is being administered. In one case of ischio-rectal abscess in which a deep sinus had persisted for weeks, and in which the injections, though otherwise beneficial to the patient, had not caused healing, administration of calcium by the mouth three times a day for thirty-six hours was followed by cessation of pus formation; the packing was taken out, and the sinus healed in a few days. In the case of children with persistent febrile temperatures the action of this drug given by injections is little short of wonderful, and in surgical tuberculosis it would seem in these northern latitudes to be able to take the place of heliotherapy.

With regard to the administration, I am of opinion that where injections are given it is quite sufficient to give 0.5 c.cm., and after the first injection it is well to wait a week to see if there is any reaction, as there seems little doubt that in some cases this drug either extracts toxins from the bacilli or else produces absolute lysis of the bacilli; indeed, this may be one of the causes of the benefit which ensues. In a number of cases the injections do not need to be given oftener than once a fortnight. In acute febrile cases caution is required, and smaller doses should be used or small doses of calcium by the mouth administered. As a rule, 0.5 c.cm. is sufficient to stop haemorrhage.

If medical men would treat their suspected cases by this method a great deal of avoidable sickness would be prevented, and if it were tried on chronic cases often great amelioration of symptoms would be produced.—I am, etc.,

New Cumnock, July 1st.

EDWARD E. PREST.

BONE-GRAFTING IN TUBERCULOUS SPINAL
CARIES.

SIR,—Among Sir Henry M. W. Gray's most interesting remarks in favour of bone-grafting in tuberculous spinal caries occur several statements open to serious criticism, to which I feel bound to call attention.

1. He states that "fixation is essential to success"; and then that "all are agreed on the difficulty of fixing the spinal column efficiently by external splinting so that movement is entirely prohibited." Let me say at once that fixation in the sense in which he uses it here is not essential to success, and that therefore the difficulty he alleges does not arise. Dr. Rollier at Leysin, between the years 1903 and 1913, treated 198 cases of Pott's disease, of whom 171 were cured, and in no case did he attempt such fixation; what he did try to obtain was physiological rest, which is prevented by absolute fixation.

2. Sir Henry Gray states that in six to twelve months after the operation the patient may be leading a normal life except for the slight restriction imposed upon him by the stiffness of the part operated upon, and that therefore by operative fixation much time is gained for the patient when compared with fixation by external splinting. At first glance he does seem to have found here a valuable argument in favour of the operation, for the average period of treatment by heliotherapy is twelve to eighteen months, but he ruins it at the end of the same paragraph by excluding from his statement all cases with abscess. He says:

"If abscess has developed the time taken in the process of cure largely depends on the behaviour of the abscess, which is uncertain. Until the abscess in connexion with the vertebral bodies is cured no relaxation of treatment (that is, fixation by external splints) should be allowed."

Now, if any large number of cases of Pott's disease be investigated it will be found that abscess is present in a very large percentage; thus in Rollier's 198 cases there was abscess in 95, or 48 per cent; so that on Sir Henry's own showing, even if he is right, nearly half the cases would not be cured any quicker by operative methods.

3. He states that in his experience the operation has not proved dangerous, as only one death which can be directly attributed to the operation occurred in his series of 28 cases. He then quotes Hibbs (against himself it seems to me), with 31 deaths in 210 cases; and, not quite so bad, Meyerding, with 8 deaths in 100 cases. If we add these three sets together, 23 with 1 death, 210 with 31 deaths, and 100 with 8 deaths, we get 238 cases with 40 deaths, or 16.8 per cent. Does Sir Henry consider that an operation with such a mortality can be rightly described as not dangerous? As a contrast to the small mortality following operation he quotes (1) a statement made by Royal Whitman in 1901 that "at least 20 per cent. of all patients die during the progress of the disease"; and (2) a statement made by Lovett in 1907 that "the mortality is probably not under 33 per cent. if ultimate results are considered." Could he have not quoted from a more up-to-date book, as, for example, Rundle Short's *Index of Prognosis*, 1918, second edition, where we are told that we may take it that the mortality is about 5 to 10 per cent.?

4. He states that operation should be done before deformity occurs, but he surely must know that it is usually the onset of deformity which first draws attention to the presence of disease. If deformity be present he tries "by postural methods to bring about gradual straightening." "If these fail, and they frequently do," he deliberately breaks the grafts, to adapt them accurately to the curvature. It is not surprising that the postural methods frequently fail, for how can he give them any chance when his advice is: Perform the operation "as soon as possible after the disease is diagnosed"? As regards leaving the deformity alone, is not this absolutely a retrograde step? Rollier has shown that in all active cases the deformity can be entirely reduced except in the cervical and lower lumbar regions. Can we then advise patients to have an operation to cure (sic!) them, and thereby force them to remain humpbacked for life, when another form of treatment can make them perfectly straight?

5. He states that by reason of the bony fixation the patient is less likely to suffer from local recurrence of the disease than after "conservative" treatment. This gives the impression that under "conservative" treatment relapse is frequent. Yet if we turn to Dr. Rollier's published statistics we find that between the years of 1903 and 1913, out of 171 cases of Pott's disease cured, there were only 2 relapses.

From the foregoing remarks, I think I have made it clear that there is everything to be said against this operation, in spite of Sir Henry Gray's optimism. If anything more were needed to open your readers' eyes to the real state of affairs, let them turn to the paragraph headed "Results of Operative Treatment," where occur the following sentences:

(a) "One patient, a young weakly child, 4 years of age, died on the third day after operation."

(b) "One adult died within two months of operation from progressive disease in the spinal cord and canal."

(c) "In another adult abscess continued to increase."

(d) "In one child operated on when 6 years of age the disease has apparently been cured, but deformity has increased."

Many years ago an operation was invented for curing microcephalic idiots. The idea was that the brain could be

was that the brain could be of the cranial cavity, and so large portions of the cranium were cut away to give the brain room. Although it soon became known that many of the children died under the operation, that those who survived it ended up in asylums, and that the operation had been wrongly conceived—the size of the skull depending upon the size of the brain, and not vice versa—yet surgeons went on performing this dangerous and useless operation in ever-increasing numbers, and it was not until Dr. W. W. Keen wrote his famous paper entitled "Noli Nocere" that their eyes were opened and they were able to perceive the error of their ways. Is it too much to hope that this history may soon repeat itself?—I am, etc.,

PAUL BERNARD ROTH,
Orthopaedic Surgeon, Miller Hospital, etc.

London, W. 1, July 25th.

"DOCTORS IN COUNCIL."

SIR,—The *Manchester Guardian* had a leader last week under the above title dealing with the deliberations of the Representative Meeting at Glasgow. Part of the leader dealt with the future of voluntaryism at hospitals and the position of the doctor in relation to any new arrangement of hospital affairs, and in this part it expressed the opinion that the discussion at the Representative Meeting was "unsatisfactory . . . because so much of it draws a kind of formal veil between us and realities." It went on to say that:

"Appointments on the staff of a great hospital are nominally honorary, but not really so, for, though they are unpaid, they are the recognized entrance gates to the most lucrative fields of private practice."

This view, which is, I believe, common to the laity, deserves more attention from the profession that it has yet received, for it will seriously interfere with the carrying through of hospital reform, and with the status of the staff of the hospital when reform is carried.

I wrote the enclosed letter to the *Manchester Guardian*, and it was published on July 28th; but as it pertains to matters which I believe are of still more importance to the medical profession than to the laity, and as it will become more and more necessary for the profession to educate the laity on this question, I am in hopes that you will consent to publish it along with this letter.—I am, etc.,

York, Aug. 1st.

PETER MACDONALD.

THE VALUE OF HOSPITAL STAFF APPOINTMENTS.

To the Editor of the *Manchester Guardian*.

SIR,—In your generally well-informed leader of the 24th on "Doctors in Council" there runs through that part of it concerned with the position of voluntaryism the thought that the position of the honorary staff in voluntary hospitals is not essentially honorary, inasmuch as indirectly it is a source of emolument. In your own words "appointments on the staff . . . are the recognized entrance gates to the most lucrative fields of private practice." As this view, which is a common one, interferes largely with what I am convinced is the sound line for hospital reform, I trust you will allow me to comment upon it.

While there is a large although varying amount of truth in it, varying with the hospital concerned, it is on the whole misleading and indicative of lines. The first is that it actively in the few, although, of a large centres, and schools. Here positions on the honorary staff are exceedingly valuable and indirectly lucrative, and far more than repay the services given in these positions. This relationship, however, between value of position to the member of the staff and value of his services to the community is not a constant one, but varies with the geographical position of the hospital, and the more peripheral (so to speak) the hospital is the lower becomes the value of the position on the staff relatively to the service—this even in the same city—until in the small hospitals in the smaller centres of population the value of the services far and away outweighs the indirect value of position on the staff. Now these smaller hospitals are

becoming, if they are not already, by far the most important class of hospital to the community, for even in the large cities the tendency is, or soon will be, to decentralize, and it is conditions at these, which should set the pace, and which should have the chief consideration in regarding the future, and not the conditions in the large hospitals, which bulk so largely in the public mind, and in your own also, if one may judge from your leader.

The second indication of confused thinking in your leader is that it fails to recognize that where hospital appointments are valuable to the holders they are so, not so much in themselves as in the fact that others are shut out from holding them; and unquestionably there has been and still is found evidence of action by honorary staffs which indicates a subconscious if not conscious endeavour to keep hospital appointments within a sacred ring. There is, in fact, a vested interest in voluntarism which subconsciously interferes with the possibility of those who arrive at "the most lucrative fields of private practice" being able to have an open mind on the question.

This state of affairs is unlikely to persist; many things are tending to break it down, among them the recognition by some of us doctors that it is in the interest of medicine, of the doctors, of the community, that the largest possible access to hospitals, and not the least possible, should be given to doctors generally. Further, the nation may presently begin to recognize that public health demands the increase of hospital beds from 1 per 1,000 to 3 per 1,000 of the population, as Sir Napier Burnett advises, and with this the monopoly value of hospital appointments will largely disappear.

Your paper is generally so wise on the great public questions that I trust you will at least give this matter further consideration, and that you will recognize that the "doctors in council," though as yet only groping for a policy, may be groping towards the light.

—I am, etc.,

Ouse Lea, York, July 26th.

PETER MACDONALD.

STERILIZATION OF MENTAL DEFECTIVES.

SIR,—The correspondence on this subject initiated by Colonel Lister ought to fulfil a very useful purpose. The proposal is one which appeals to a great many people, and its apparent advantages warrant full discussion and unprejudiced consideration.

It is certainly unfortunate that already arguments diametrically opposed are being employed, based on differing reports of American experience. Mr. Norman Hairo refers in the *Journal* of July 15th (page 110) to the "methods so widely and beneficially used in the United States," and presents a very different picture from that given by Dr. Whitwell a week previously.

If it be true that sterilization by any method is used "widely and beneficially" in America, then an extremely powerful argument is provided for those who desire to introduce the procedure into this country. Last week I had the pleasure of meeting a New York hospital surgeon, a delegate to Enrope of the American Red Cross, who takes a deep interest in all problems affecting the health of the community, and his opinion is that the results of sterilization of mental defectives in the United States are negligible.

In view of such a conflict of opinion it seems very desirable that statistics from America should be ascertained and published so that there may be some authoritative basis for discussion. It should be possible to find out for each State:

- (a) For how many years the law under which these operations may be performed has been in force?
- (b) Whether permission is required from the mental defective or relatives before sterilization can be effected?
- (c) The total number of operations.

I hope this will be done.—I am, etc.,

Gloucester, July 16th.

W. ARNOTT DICKSON.

SIR,—I was a school medical officer for two years in a large English county. In nearly every school I inspected there were from one to five or six mentally defective children, according to the numbers attending. There were others either quite imbeciles or epileptics not actually attending school. I feel that everyone who has been a school medical officer will support the plea of Lieut. Colonel A. E. J. Lister, contained in his letter of July 1st, as to the necessity of taking effective steps to prevent the increase of these unfortunate people.

In one school I had a mentally defective boy of 13 years of age. He could learn nothing and could not even speak intelligibly. His mother came to me complaining bitterly that it was hard that he could not leave school to go to work. She did not in the least realize that he was mentally defective, because she said, "When I was at school I could never learn anything myself."—I am, etc.,

Clifton, Bristol, July 24th.

L. MARGARET LISTER,
M.R.C.S., L.R.C.P.

THE DENTISTS ACT AND REGISTER.

SIR,—There is reason to think that the postponement of the date on which the Dentists Act, 1921, will come into force from July 28th until November 30th this year has given rise to some misapprehension. I am therefore directed to write and say that any practitioner who has been registered comes within the jurisdiction of the Board, and should pay very careful attention to its warning notice in regard to advertising and canvassing. The extension of the Act does not permit any relaxation in regard to this.

It is possible that there are some practitioners who have been notified that they are eligible for registration who are refraining from completing their applications in order that they may be able to continue the practice of advertising and canvassing. If any such cases were brought to the notice of the Board this matter might have a bearing on the question of good personal character.

There are some practitioners who have in their employment assistants who are intending to pass the prescribed examination as soon as they can. The Board would be unwilling that these unregistered assistants should be penalized. At the same time the warning notice in regard to "covering" must be observed, and such assistants should confine their work to mechanical duties or to matters which do not require professional discretion or skill, and should perform them only under the immediate personal supervision of their employers.

I have to add that the concession that ex-service candidates may count work done up to July, 1922, instead of only to July, 1921, has no bearing upon the eligibility for registration of those who had not attained the age of 23 years on July 28th, 1921. The question of age is one upon which the Act is very definite, and the Board has no discretion in regard to this matter.—I am, etc.,

London, W., Aug. 5th.

NORMAN C. KING,
Registrar.

THE MEDICAL DIRECTORY, 1923.

SIR,—The annual circular has been posted to every member of the medical profession. Most of the returns have already been received. If any practitioner has not yet sent us the latest information, we shall be glad to receive it by an early post.—We are, etc.,

7, Great Marlborough Street, London, W.1,
Aug. 2nd.

THE EDITORS.

Obituary.

ARTHUR RANSOME, M.D., M.A., F.R.C.P., F.R.S.

THE death of Dr. Arthur Ransome on July 25th, at the age of 88, has robbed the medical profession of one who brought it honour in many ways. He was the son of Mr. J. A. Ransome, and was born in Manchester. He received his early education at Manchester, went first to Trinity College, Dublin, and later to Caius College, Cambridge, of which he subsequently became an honorary Fellow. His career at Cambridge was distinguished. He was senior optime in the Mathematical Tripos, and in 1856 took a first class in the Natural Science Tripos; he was lecturer on biology from 1857 to 1861. From Cambridge he went to St. George's Hospital, London, and studied also in Paris. From 1860 to 1865 he was successively lecturer and professor of hygiene and public health at Owens College, Manchester, and for many years he was consulting physician to the Manchester Hospital for Consumption and Diseases of the Chest and Throat; later on he became physician to the Royal Victoria and West Hants Hospital. He was Vice-President of the Manchester and Salford Sanitary Association, and examiner in sanitary science at the Cambridge and Victoria Universities. In 1890 he delivered the Milroy lectures before the College of Physicians, when he took the etiology and prevention of phthisis as his subject. In 1897 he was the first recipient of the Weber-Parkes prize for an essay on tuberculosis.

This record gives but an inadequate impression of the achievements of a man who did fine pioneer work in connexion with the prevention and treatment of tuberculosis, and attained a reputation of cosmopolitan range. Arthur Ransome belonged to that not inconsiderable class of men who add much to the sum total of human knowledge but whose identity becomes merged in their work, so that posterity is apt to forget how great were their services. Ransome's gifts were great and many, and though he may not have laid any corner stone, his was the valuable work which fills in important gaps in the masonry, giving to it support and cohesion.

comparatively early in his career he began to be interested in tuberculosis, and almost all his subsequent publications dealt with this subject. As early as 1876 he published a monograph on stethometry, and it is eloquent of the solid character of his work that it is still quoted in modern textbooks of diseases of the chest. In 1882—the year signalized by the discovery of the tubercle bacillus by Koch—Ransome published a valuable work on prognosis in lung disease, and two years later followed this up by an essay on the causes of consumption. Unlike many specialists in tuberculosis at this time, he did not take a partisan attitude with regard to the conflict raging over the respective merits of the “soil” and the “seed” in the causis of this disease, for he was convinced that both played an important part. This capacity to see more than one side of a case at a time was characteristic of a man of many parts. For not only was he a mathematician and biologist, but he was also an anatomist and a chemist (he was Caius scholar in anatomy, and Meekdenburg scholar in chemistry). Apart from the question of personal predisposition to tuberculosis, insanitary conditions were, in his opinion, an important factor; he once stated that he had never come across an instance of infection, direct or indirect, in a well-ventilated house in this country; where illness followed infection the rooms were always dark, dirty, and ill ventilated. He also showed that during the warmer part of the year tubercle bacilli can grow on damp wall-paper, and that a permanent source of infection might exist in this way. One of his experiments, which still stands as a specimen of first-class research, was in connexion with the action of sunlight on the tubercle bacillus. He exposed some virulent sputum to fresh air and sunlight on dry, sandy soil, and though the exposure was not long enough to pulverize the sputum, none of the specimens remained virulent. Other specimens, kept in a dark cupboard with very little air, remained virulent for nineteen and thirty-five days respectively, as shown by inoculation of guinea-pigs. When specimens were exposed to currents of air in the dark, their virulence was reduced, but to a less degree than by sunlight. In 1890 he again published a work on the causes and prevention of phthisis, and as late as 1914 he was adding useful contributions to our knowledge on this subject. We have already referred to his cosmopolitan reputation, and in Germany, at any rate, he was recognized as not only an authority, but a pioneer, in the study of tuberculosis; he was for many years, and up to the time of his death, an associate editor of *Zeitschrift für Tuberkulose*.

Though his sphere of activities was in the provinces, the last thing to be said of his work and outlook was that they were provincial. Indeed, much of his best work appeared at a time when it could with some justice be said that the attitude of his colleagues in London towards tuberculosis was a trifle reactionary, if not provincial, and he enjoyed the doubtful privilege of being ahead of his time, and more than a head and shoulders above the crowd.

EDWARD HUGH EDWARDS STACK, M.B., B.Ch.CANTAB., F.R.C.S.Eng.

WE regret to learn of the death of Mr. E. H. E. Stack of Clifton, Bristol, which occurred on August 3rd in London, at the age of 55. He was the third son of the Rev. Canon Stack, and was born at Langfield, co. Tyrone. He received his education at Haileybury, Pembroke College, Cambridge, and St. Bartholomew's. In 1892 he took the Conjoint qualification and the degrees of M.B., B.Ch.Camb. In the same year he won the Brackenbury Medical Scholarship at St. Bartholomew's and became house-physician to Dr. Gee. He subsequently held the posts of ophthalmic house-surgeon as well as extern and intern midwifery assistant. In 1897, after obtaining the F.R.C.S.Eng., he was appointed house-physician at the Bristol Royal Infirmary and later (1902) house-surgeon. In 1906 he was elected assistant surgeon, and in 1914 surgeon, to the Bristol Royal Infirmary. On the death of Dr. Alexander Ogilvy in 1914 Mr. Stack was appointed ophthalmic surgeon, and devoted himself entirely to this special branch of surgery during the remainder of his life.

In addition to his appointments at the Royal Infirmary Mr. Stack was surgeon to the Bristol Eye Hospital and consulting surgeon to the Cossham Hospital; for many years he had been surgeon to the Bristol Orthopaedic Hospital. He served as Captain R.A.M.C.(T.F.) during the war, and did

excellent work as ophthalmic specialist at the 2nd Southern General Hospital in Bristol and at 56 General Hospital in France.

To few men has it been given to master so readily and to excel in any branch of clinical medicine that he essayed. Whilst in residence at the Bristol Royal Infirmary his successful coaching in midwifery seemed to point him out as a rising obstetrician. As a physician his clinical acumen and powers of diagnosis were remarkable, and no small part of his success as a surgeon might be attributed to his sound knowledge of internal medicine. He chose, however, the practice of surgery, and in this branch of the profession his skill in carpentry and wood-carving stood him in good stead; he had the perception of an artist combined with the hand of a craftsman. When in 1914 he turned to ophthalmology he soon showed that the teaching and example of Henry Power and Bowater Vernon were not forgotten. He was a neat operator, a gifted refractionist, and, above all, displayed a singular grasp of the medical aspects of eye diseases.

Throughout his life his enthusiasm for the welfare of the medical students had been intense. He was passionately loyal to his old hospital—Bart's—but was scarcely less devoted to Bristol, the school of his adoption. In athletics, in amateur dramatics, and in all the social activities of the medical school Stack was a leader and a mighty encourager of youth; and he spared himself neither time nor labour in teaching. His grinds and ward classes were always well attended, for he added to the knack of clear exposition a fund of apt anecdote that helped to fix the duller facts in the duller minds. His memory for patients' faeces, names, and ailments was unequalled; it was said that he had on one occasion recalled a patient's name, address, and whole family history from mere inspection of the scar of an operation wound.

Stack was a warm-hearted impulsive Irishman, who made friends wherever he went. His early death will be widely and deeply mourned. He leaves a widow, three sons, and a daughter, to whom our heartfelt sympathies are offered.

WE regret to record the death of Dr. JOHN MAITLAND FORSYTH, M.C., which took place at Singapore on June 26th. He was the only son of Robert C. Forsyth, of Taiuanfu, North China, and graduated M.B., Ch.B. at Glasgow University in 1912. He was a captain in the R.A.M.C. during the war, his gallantry being twice recognized by the award of the Military Cross and bar. In 1920 he went out to Singapore to join Dr. Galloway in partnership, and during his two years' residence there he made many friends and earned the esteem of all. He was a prominent member of the local Branch of the British Medical Association and its representative on the Medical Council of the Straits Settlements and Federated Malay States.

CAPTAIN N. N. G. C. McVEAN, I.M.S. (ret.), died aged 42, on July 21st, at the house of his brother-in-law, Major H. B. Luard (I.M.S. ret.), at Little Baddow, Chelmsford, after a month's illness; he was buried on July 26th in the family grave at Oban, Argyllshire. He was the youngest son of the late Colin A. McVean of Kilfinichen, Isle of Mull, and was educated at Watson's College, Edinburgh, and Edinburgh University, and entered the Indian Medical Service in 1905, serving in the Punjab and afterwards in the Gulf of Persia as agency surgeon. When the war broke out he proceeded with the 62nd Punjabis to Egypt, when he was present in the action at the repulse of the Turks on the Suez Canal, and afterwards at Aden, whence he was invalided home in 1915. For the last seven years, after several operations, he led a life of much suffering in a state of extreme emaciation, borne with wonderful fortitude and good cheer. He had a very active mind and an indomitable spirit, which overcame the lassitude and exhaustion of his invalid state, and almost to the end continued to take an active part in his profession, acting as assistant in various practices, or on Pension Boards in London, or in hospitals, including, during the latter part of the war, service as a civilian practitioner at the Colchester Military Hospital, and in V.A.D. Hospitals at Bournemouth and at Glasgow. It may truly be said that he died for his country, and was an ornament to his distinguished service, in which he will be remembered by many friends as well as in this country, for he had a wonderful gift of friendship. He rests under the shadow of his native Highland hills, which he loved so well.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a Congregation held on August 4th the following degrees in medicine were conferred:

B.M., B.Ch.—D. G. Leys, W. S. Tanbridge.

Degree days for next term are announced as follows: Thursday, October 19th; Thursday, November 2nd; Saturday, November 18th; Thursday, November 30th; Saturday, December 16th.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on July 19th.

The following were recognized as teachers of the University at the institutions mentioned and in the subjects indicated:

University College: Mr. J. L. Shellshear and Mr. R. A. Dart (Anatomy). St. Thomas's Hospital Medical School: Mr. T. Carnwath (Hygiene), Mr. P. H. Mitchiner (Surgery), Mr. W. Rushfor (Biology). London (R.F.H.) School of Medicine for Women: Miss Emily C. Lewis, Mr. L. E. C. Nohury, Mr. C. E. Shattock, and Mr. C. A. Joll (Surgery).

Dr. W. L. Symes was re-elected acting director, and Mr. H. L. Eason, C.B., C.M.G., M.S., treasurer of the physiological laboratory for 1922-23.

Professor A. J. Clark was appointed chairman of the Board of Examiners in pharmacology for the second examination for medical degrees for the year 1922-23.

Professor Adrian Stokes, D.S.O., O.B.E., was admitted to the Faculty of Medicine.

The following grants were made for 1922-23 out of the Thomas Smythe Hughes Medical Research Fund:

£100 to Dr. Charlotte L. Houlton, of the London (R.F.H.) School of Medicine for Women, for an investigation of vaginal secretions with a view to the discovery of some prophylactic method for the prevention of puerperal infection.

£25 to Dr. Vasant Ravi Kharolkar, of University College Hospital Medical School, for an investigation of the presence of non-specific antibodies against proteina with a view to further insight into the nature of non-specific immunity.

It was decided that, in and after October, 1922, the clinical examination in surgery at the M.B., B.S. examination be so arranged that each candidate shall have thirty minutes for examining two cases before he is questioned on them by the examiners, and that the length of the clinical examination be in all forty-five minutes.

Human anatomy has been added to the list of subsidiary subjects that may be offered at the choice of the candidate at the B.Sc. Honours examination on physiology for external students.

The Vice-Chancellor, Mr. H. J. Waring, has been elected chairman of the Co-ordination and Developments Committee for 1922-23.

Dr. T. G. Stevens has been appointed a staff examiner in obstetric medicine for 1922-23.

Medical News.

THE French Minister of Health, M. Paul Strauss, who is in London in connexion with the holidays of French children from devastated areas, is taking the opportunity of studying public health administration in this country. He was entertained at lunch by the First Commissioner of Works on Thursday last, when Sir Alfred Moud was in the chair.

A DEPUTATION from the People's League of Health waited on Sir Montagu Barlow, Parliamentary Secretary to the Minister of Labour, on August 2nd, to place before him some of the physiological and psychological effects of unemployment and of the "dole" upon the health and habits of the industrial community. Sir Bruce Bruce-Porter said that not only was the unemployment benefit insufficient to keep the worker fit, but it was not spent to the best advantage because the recipient was generally unversed in food values. He urged that means should be provided to enable the recipient to obtain by means of food tickets a standard balanced diet in part substitution for the money benefit. Professor Lyle Cummins dwelt upon the connexion between unemployment with its reduced income and ill health as instanced by the number of persons applying for tuberculosis benefit during times of industrial crisis or depression. Dr. W. A. Potts of Birmingham traced certain psychological disorders, which manifested themselves either in revolutionary agitation or in moral delinquency, to ill health caused by insufficient food. Sir Montagu Barlow said that while he fully appreciated the serious effect produced on health by prolonged unemployment, he thought that there would be danger of the improper use of the proposed food tickets, and that elaborate supervisory machinery would be required. Captain Donald Simson, who represented the British Legion, outlined a scheme whereby the sums now spent on unemployment benefit might be diverted into productive channels; the benefit would be paid to local authorities or private employers to cover partly

the wages of unemployed men whom they had taken on. This scheme was supported by Dr. Fremantle, M.P.; and Mr. C. J. Bond spoke of the measures taken by the Leicester Distress Committee to institute public works, such as road widening, in order to provide for the unemployed; the secret of success in this instance lay in the integration of a certain amount of highly skilled labour with the unskilled. Sir Montagu Barlow reminded the deputation that the insurance fund was made up largely by the contributions of workpeople who were still in employment. These had contracted under the scheme for the payment to them of benefit when unemployed, and as trustee of the fund the Government, except by amendment of existing legislation, could not divert sums in its charge to purposes other than those provided under the scheme. He added, however, that schemes on the lines of Captain Simson's proposal were under the consideration of the Government.

THE principal functions of the Health Organization of the League of Nations, which was established in September, 1921, are to conduct an international epidemiological information service and to promote international co-operation in the control of epidemic diseases. It also advises the League in matters affecting health and co-operates with the International Labour Organization in promoting industrial hygiene. The International Health Board of the Rockefeller Foundation has now agreed to provide the Health Organization of the League with a sum of £10,000 per year for a period of five years to service, and a further sum not exceeding £5,000 per year for three years to put into effect the scheme for the international exchange of public health personnel, to which we recently referred.

THE Association of Medical Officers of Fever Hospitals has decided to join the Society of Medical Officers of Health as the Group of Medical Officers of Fever Hospitals. At a meeting of the group held on July 31st Dr. E. W. Goodall, O.B.E., North-Western Hospital, Hampstead, was elected president, and Dr. A. F. Cameron, Joyce Green Hospital, Dartford, Kent, honorary secretary of the group. Candidates for election as members of the group are asked to send their names to the honorary secretary as soon as possible in order that they may be included in the list of members for the coming year which is now being prepared.

THE programme of the forthcoming session of the Medical-Legal Society has been issued by the honorary secretaries, Mr. Ernest Goddard and Mr. B. H. Spilsbury. The first meeting will be held on October 17th and the annual dinner on December 15th. At the annual general meeting held last month it was resolved unanimously that the annual subscription be raised to one guinea, with effect from the beginning of next year.

ON the occasion of his retirement from the acting honorary staff of the Stratford-upon-Avon Hospital, Dr. R. Latimer Greene was presented with a silver salver, a cheque for £175, and a book with the names of the subscribers, in recognition of his services to the hospital for upwards of forty years. The governors have appointed Dr. Greene honorary consulting medical officer to the institution.

THE Ashby Memorial Research Scholarship in Diseases of Children of the University of Manchester has been awarded to Miss Ruth E. Conway, M.B., Ch.B. Manch., M.R.C.P., who will undertake an investigation into the reaction of the blood and its relation to the bicarbonate content in cases of clinical acidosis—(1) in relation to anaesthesia, (2) in relation to diabetes in children.

MR. H. C. DYSON, of Epsom College, has been elected to the Epsom Scholarship, tenable concurrently with the Carr Scholarship from Epsom College at University College, London.

AN international conference of medical women will take place at Geneva during the first week of September. The first congress was held in New York in 1919. The authorities of the University at Geneva have kindly granted accommodation for the meetings of the conference. Subjects of international medical importance on which the opinions of medical women of the world should prove of value will be considered. The members of the conference will also be invited to place the constitution of the International Medical Women's Association on a permanent basis. The proceedings will begin with an inaugural banquet on September 4th, and will extend for four or five days.

THE golf competition under handicap for the Llandrindod Wells Medical Challenge Cup, value 50 guineas, will take place on September 20th, 21st, and 22nd. The entrance fee is 5s., and the competition is limited to qualified medical practitioners. Entries, which will be received up to the first post on Tuesday, September 19th, should be sent to the Secretary, Golf Club, Llandrindod Wells. Further details will be found in our advertisement columns.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

TREATMENT OF CYSTITIS IN PARAPLEGIA.
S. J. C.* recently treated cystitis following catheterization, for retention in a case of spinal paralysis, by perineal urethrotomy, cutting down on to a grooved staff where it entered the bladder. A large rubber catheter was kept in through the perineal wound for a couple of days and a sound passed by the urethra and the

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

90. Pyuria in Children.

J. S. FOWLER (*Edinburgh Med. Journ.*, July, 1922, p. 1) records his experience of 76 cases of pyuria in children with a view to ascertain to what extent the clinical and bacteriological findings are a guide as to whether any given case should be referred for surgical investigation or whether it will probably respond to medical treatment alone. Acute cases are most frequent in infancy, and the condition is much more common in girls than in boys, its occurrence in the latter being more likely to be of a serious nature, so that the prospect of a necessity for surgical treatment is greater. Bacteriologically the coliform group of organisms predominates, though in chronic cases repeated pure cultures of *B. coli* are no proof that it is the only infection, and in cases of stone or tubercle its absence is of more diagnostic value than its presence. In the diagnosis between grave and benign types of the disease the following seven points should be borne in mind: male sex; large quantities of pus; presence of blood in the urine; palpable enlargement of the kidney; continued tenderness in the loin; presence of organisms other than the coli group; and hæmaturia. Attempts to distinguish between cystitis and infection higher up are of little value since frequent painful micturition may be met with in either type, and pain in one or other loin, beyond pointing to the kidney involved, often exists in cases which recover well on complete rest and urotropine. The presence of casts is more suggestive of calculus than of either pyelitis or renal tuberculosis, and though in the latter the tubercle bacillus is only rarely found early diagnosis is essential since it usually only affects one kidney, and the results of nephrectomy are very satisfactory. Of the benign cases only one was fatal, meningitis developing as a separate condition some weeks later, showing the necessity when diagnosis is in doubt of excluding meningitis by lumbar puncture. While fretfulness and irritability accompany pyelitis in quite young children, they are not so characteristic in older children at the age when meningitis is more common. Medical treatment consists in rest in bed, abundant fluids, with urotropine in chronic cases and alkalis in acute cases, surgical treatment being considered in long-standing obstinate cases even in the absence of definite proof of stone or tubercle.

91. Intolerance of Emetine.

SANFILIPPO (*Il Morgagni*, June 5th, 1922, p. 245, and *Stadium*, November 20th, 1921) reports three cases where unusual effects followed the use of emetine. (1) A case of amoebic dysentery treated with emetine for some time without any bad effects and cured of the dysentery, but later (forty days after) amoebae were again found, and five capsules of emetine and bismuth were given (one capsule per diem). Immediately after the fifth a sudden complete amaurosis set in, unaccompanied by any other disturbance. The blindness disappeared in about forty-eight hours without leaving any sequelae. (2) A case of amoebic dysentery. After 12 g. of emetine had been given a sense of precordial discomfort arose, the pulse came down to 40 (from 60), the knee-jerks were abolished, and there was marked motor weakness. The symptoms were relieved by adrenaline and spartein, but the bradycardia persisted. In the third case (amoebic dysentery with non-suppurative hepatitis) the chief irregular result of emetine was elevation of temperature unaccompanied by local symptoms.

92. High Blood Pressure without Renal Disease.

F. KÜLS (*Deut. med. Woch.*, June 2nd, 1922, p. 717) finds pressures of 160-200 mm. of mercury comparatively frequent, even in the absence of signs of granular kidney. Among 288 patients, 172 of whom were men, he has observed pressures not less than 170-180, and in none of these could albumin or cells be found in the urine during an observation period of months and even years. In about 20 per cent. this high pressure was unassociated with subjective discomfort. Among the remainder, the chief symptoms were palpitation of the heart, shortness of breath, insomnia, a sense of pressure within the head, epistaxis, and hæmorrhoids. The cases are thus classified: (1) mental stress and excitement, 75 cases; (2) climacteric disturbances, 65 cases; (3) syphilis, 50 cases; (4) nicotine poisoning, 39 cases; (5) alcoholism, 19 cases; (6) adiposity, 16 cases; (7) gout, 8 cases; (8) organic heart

disease, 7 cases; (9) bronchial asthma, 5 cases; (10) plethoræ, 4 cases. Among the syphilitic cases the prognosis was bad, and 13 of the 50 patients had already died. Almost two-thirds of the nicotine cases were greatly benefited by the withholding of tobacco, pressures about 180 falling to 150 or 140. Among the patients suffering from adiposity, great relief was obtained by reducing their weight. The pressure among the cases of gout could not be reduced below 170, although symptomatic improvement was effected by general and specific treatment. The age period at which high pressure was most common was between 50 and 60, and educated persons were much oftener subject to this condition than the working classes. Under treatment with rest, a diet deficient in salts, venesection, and small doses of digitalis, the author succeeded in reducing the pressure in most of his cases to 150 or 160 mm. with, as a rule, improvement in the general condition.

93. Haemophilic Arthritis.

MONTANARI (*La Chirurgia degli Organi di Movimento*, April, 1922, p. 214) reports, with illustration, 13 cases of arthritis due to hæmophilia. The knee is the commonest joint affected, and is usually first noted about the fifth or sixth year. Injury is generally the starting point. In one case the effusion recurred no less than thirty times. Onset is rapid and not very painful, and walking is, as a rule, not much interfered with. Periarthritic ecchymosis may or may not be present; the temperature of the affected joint is slightly raised. Absorption may take place rapidly or very slowly, leaving a permanently damaged joint. Except for a greater density in the shadow it is doubtful if radiographic examination helps much in the differential diagnosis. All the author's cases were male; in 6 heredity played a part. Amongst other theories as to the etiology possibly the state of the "interstitial gland" may play some part. The condition should be differentiated from trophic hæmarthrosis (hemiplegia is then present), scurvy rickets, rare hæmorrhagic and traumatic synovitis (here the injury is much more severe). The prognosis *quoad vitam* is favourable, but poor as regards local function. Operative interference is out of the question. If there is excessive effusion some may be drawn off by trocar, otherwise treatment is limited to support of the joint and conservative measures.

94. The X-Ray Treatment of Graves's Disease.

FISCHER (*Ugeskrift for Læger*, April 13th and 20th, 1922) has treated 490 cases of Graves's disease with the x-rays, and has effected either recovery or definite improvement in about four-fifths of the total. In the remaining fifth no harm was done, and in the one case in which death occurred six days after an exposure this could certainly not be held responsible. The results were much better in the author's private practice than among his hospital patients, many of whom relapsed because they could not avoid overwork and worry. Only 11 patients were males, and the average age of the females was between 30 and 45. Particularly good results were obtained in early or abortive forms with marked nervous symptoms and only slight tachycardia, whereas the results were rather disappointing when the clinical picture was dominated by tachycardia and the enlargement of the thyroid and the nervous symptoms were slight. The author pleads for x-ray treatment at an early stage, and is convinced that it does not interfere with subsequent operative treatment by provoking adhesions around the gland.

95. Torsion Spasm.

ACCORDING TO R. MOURGUE (*Gaz. hebdomadaire des sciences médicales de Bordeaux*, May 23rd, 1922, p. 254), who records a case following lethargic encephalitis, torsion spasm described by Kurt Mendel under the name of *Torsionsdystonie* is an extremely rare condition. The great majority of cases hitherto recorded have occurred in Russian Jews, especially natives of Galicia. Its occurrence after infectious diseases, such as typhoid fever, malaria, and whooping-cough, or after slight trauma, is not uncommon, but no case has previously been reported after lethargic encephalitis. The symptoms consist of muscular hypotonus during rest, and in the development of hypertonus when the patient walks upright, hypotonus reappearing when he crawls along the ground, lumbar lordosis, forward projection of the pelvis, distortion of the trunk in relation to the axis of the body, varo-equinus position of the foot in walking, choreo-athetoid movements, and hepatic insufficiency without clinical signs.

96. Treatment of Soft Chanores by Local Application of "914" (Novarsenobenzol).

H. MARCHAND (*Lyon Médical*, June 10th, 1922, p. 469) states that chemical caustics or antiseptics, or the thermo-cautery, when used in the treatment of soft chanore, require three or four weeks of painful treatment to effect a cure. The author has been using "914" as a local application, with entirely satisfactory results, during the last eighteen months. His method is as follows: A 15-gram ampoule of arsenobenzol is opened and the contents immediately dissolved in 5 c.cm. of boiled or distilled water, giving a 3 per cent. solution. A small tampon of absorbent cotton is saturated in this and applied to the surface of the ulcer for five to ten minutes, care being taken to wash all irregularities, and especially the edges of the ulcer, with the solution. This lavage being completed, a pad of absorbent cotton-wool, saturated in the same solution, is then applied and allowed to remain in contact with the ulcer for some hours. The patient then washes it with boiled water and covers the chanore with dermatol or aristol to prevent infection of the surrounding skin. Next day he bathes the ulcer with dilute H_2O_2 solution and again applies the powder. On the second day a fresh application of "914" solution is made, and the treatment is repeated at the same intervals until the cure is complete. Even old and extensive ulcers have been healed in from thirteen to fifteen days; a chanore as large as a florin has been sterilized and cicatrized in six or seven days. Marchand remarks that the treatment is usually painless, but in cases where there is much inflammation he applies a 1 in 30 solution of cocaine for a few minutes before commencing the swabbing of the ulcer. In addition to the painless nature of the treatment, he claims that the rapid sterilization of the ulcer prevents adenitis; none of his cases treated by this method have developed a bubo. The author gives details of five cases which confirm his statements in regard to rapidity of cure and absence of complications arising during treatment.

97. Lumbago and Sciatica.

AIKOLI (*Rif. Med.*, May 22nd, 1922), in a review of the above conditions, refers to a series of 1,578 cases recorded by Lindstedt. One group could be correlated into various articular or spinal deformities, inducing a disturbance of the dorso-lumbar muscular mechanism. Some cases seem due to excessive muscular exertion. Others may be due to changes in the nervous supply of the muscles. Sciatica is not a constant clinical entity but rather a symptom complex not precisely definable. Many cases of sciatica are associated with definite lesions of the neighbouring organs, and might be looked on as a neuralgia from irradiation, or reflex, comparable to trigeminal neuralgia.

SURGERY.

98. Removal of Ureteric Calculi by the Cystoscope.

LÉON THÉVENOT (*Arch. des mal. des reins et des organes génito-urinaires*, April 1st, 1922, p. 56) points out that the cystoscope may be used not only for catheterizing the ureter as an exploratory procedure, but also to dislodge foreign bodies causing an obstruction to the flow of urine. Owing to the improvements in the cystoscope, the results obtained in this manner are most encouraging. This plan has been employed chiefly in relation to renal and ureteric calculus, and the expulsion of calculi has been produced in cases of persistent colic, calculus anuria, and where a stone has been discovered perhaps by chance. Two methods are employed—the simple passage of the ureteric catheter and the injection of anaesthetic solutions and lubricants. Cocaine or novocain may be used to abolish the spasm which prevents the passage of the stone, whilst lubricants, such as glycerin or oil, allow the stone to pass easily along the ureter. In cases of calculus anuria many successful results have been published. It is used during the stage of tolerance, and if one catheter fails another should be tried. Bilateral catheterization should be carried out as a rule; where only one side is done this should be on the painful side and the one most recently involved. When signs of uræmia are present nephrotomy must be performed. In cases of persistent colic the ureteric catheter is frequently successful in causing the expulsion of a stone into the bladder, and then it may be passed spontaneously. In the cases of calculi not causing acute symptoms, the author records a number of successes following ureteral catheterization and injections of oil. A successful result depends on the shape and size of the stone. If it is not larger than a cherry or date stone it will probably pass spontaneously. It also depends on the condition of the ureter. If it is stenosed the calculus cannot

pass. This method exposes the patient to no danger, and it is logical to try it before having recourse to a pyelotomy or ureterotomy.

99. Acute Intussusception.

R. T. THOMAS (*New York Med. Journ. and Med. Record*, June 7th, 1922, p. 656) urges that the real problem in intussusception is to make prompt diagnoses general. If the diagnosis were as easy as in appendicitis the mortality of operative reduction would probably be less than that of appendicectomy. If reduction were done in all cases within twelve hours after the onset of the condition there would probably be very few deaths. Intussusception is the great cause of acute obstruction in children, and between one-third and two-thirds of all acute intestinal obstructions occur in children. Therefore diagnosis looms large and is particularly important. The great majority of intussusceptions begin near or at the junction of the small and the large bowel. The diagnosis shows the usual signs of acute obstruction—abdominal pain, shock, vomiting, and constipation. The pain is severe and shows periodic exacerbations, whilst there may be diarrhoea or a discharge of blood-stained mucus. The temperature and pulse may be normal, and a palpable tumour may be present. The great object in treatment is to release the invagination before stasis and exudation make reduction impossible or gangrene occurs. The latter condition usually leads to a fatal termination. When simple reduction can be carried out the mortality will be about 25 per cent. It appears probable that during reduction the last part to appear was the first part to go in during the formation of the intussusception. Where it is necessary to do more than a simple reduction the mortality mounts up. Resection and end-to-end union, or formation of an artificial anus may be done, whilst lateral anastomosis above and below the intussusception may give the patient a better chance in some cases.

100. The Sex Incidence of Appendicitis.

BACKMAN (*Acta Medica Scandinavica*, April 22nd, 1922) has investigated the sex incidence of 933 consecutive cases of appendicitis operated on in the period 1903-15. He found that the males were represented by 335, the females by 598 cases, the percentages being 35.9 and 64.1 respectively. Classifying his cases according as the disease was simply catarrhal or destructive at the time of operation the author found that in the catarrhal class there were only 194 males to 465 females, whereas in the destructive class the numbers were approximately equal (141 males to 133 females). Discussing the comparative frequency of simple catarrhal appendicitis in females the author notes that in this class 50 per cent. of the females suffered from chronic constipation, whereas this was the case only in 24 per cent. of the males, and he suggests that chronic constipation is largely responsible for the genesis of catarrhal appendicitis in women. Catarrhal appendicitis terminates in destructive appendicitis more frequently in the male than in the female because the appendix of the male has a single, not a double, blood supply.

101. Steinhach's Operation and Rejuvenescence.

M. G. MARINESCO (*Journ. de méd. et de chir. prat.*, June 10th, 1922, p. 416), at a recent meeting of the Académie de Médecine, described his recent researches in continuation of the work of Ancel and Boniss, who first described the "interstitial gland" of the testis. He refers to the experiments of Steinhach (1920), who endeavoured to awaken the activity of the interstitial gland in aged rats by a resection of the vas deferens after isolating it from the blood supply of the testis. The results were in many cases remarkable: increase in weight, of activity and pugnacity, recovery of sexual powers, etc. Lichtenstern performed the same operation on three men, and this was followed by signs of general physical and mental rejuvenescence. However, the statements of Steinhach have not been confirmed by the majority of German observers. Some have come to the conclusion that suggestion played an important part; others have questioned the separate existence of the "interstitial gland." Marinesco's researches have convinced him that there is a histological specialization of the interstitial tissue, at least among mammals, and that ligation of the vas deferens produces an hypertrophy of the interstitial gland, but there our hopes must end. He performed the operation on three aged patients: two suffered from paralysis agitans and one had tabes dorsalis. He observed, at first, increase of muscular strength and of activity, with a return of sexual power, but no phenomena which justified the description "rejuvenescence." The sexual activity disappeared at the end of two months, and in one year the patients were in the same state as before. The author thinks that Steinhach's anticipations were ill founded. Senile processes do not depend on anatomical and histological

changes but on protoplasmic cellular alterations. All the organic and inorganic colloids follow an inexorable vital curve; their senescence ends in dehydration of the colloidal particles; precipitation follows agglutination. On the other hand, the theory of non-reversibility dominates biology. Growth and differentiation are essential conditions of life; differentiation once acquired is irrevocable; a differentiated cell cannot return to the embryonic form—it is condemned to die, and disappears when senility no longer permits it to fulfil its function.

102. The Incidence of Gall Stones, Post Mortem.

LIANSEN (*Ugeskrift for Læger*, April 27th, 1922) has systematically examined for gall stones the bodies of 1,191 persons over the age of 20 coming to necropsy at his hospital. He found gall stones in 293—that is, in 25 per cent. Comparing this high figure with the findings of other pathologists, he notes that their ratios have varied from 1 to 18 per cent. This lack of conformity does not depend on differences of race and other factors, but simply on the thoroughness shown by different observers in their search for gall stones. The author found gall stones in 19 per cent. of the men and in 31 per cent. of the women. In those cases in which the gall stones had induced no inflammatory reaction in their surroundings the sex incidence was practically equal. But the ratio of women to men was as 2 to 1 in the case of gall stones associated with morbid changes in the biliary system. This observation tallies with the fact that the ratio of males to females operated on for gall stones is, according to Rovsing, 1 to 4, and in hospital patients 1 to 9. In the period under review necropsies were made on 40 persons whose death was due to gall stones. In the same period only 26 persons came to necropsy whose death was due to appendicitis. Nine out of the 40 deaths occurred in medical wards. The author considers that this state of affairs reflects most discreditably on the modern treatment of cholelithiasis, which still occupies the position held by appendicitis a considerable time ago.

103. Gastrectomy for Acute Perforated Gastric Ulcer.

F. M. CADENAT (*Bull. et Mém. Soc. Chir. de Paris*, June 13th, 1922, p. 833) reports three cases of gastrectomy for acute perforated gastric and duodenal ulcer. The treatment of this condition may be simple suture, suture and gastro-enterostomy, or gastrectomy. Of the three reported cases two have been cured and one is dead. The latter case had perforated sixteen hours previously; the ulcer was on the lesser curvature and of large size. The patient was in poor condition and the writer considers he would have died anyhow. In one case where the ulcer was in the duodenum he tried to close it with a purse-string suture, but this tore out. Closure by infolding would have resulted in stenosis. As the patient's condition was good gastrectomy was performed, with a satisfactory result. The writer finds hæmorrhage which may recur after simple suture is prevented by resection. Also resection allows sutures to be inserted in healthy tissues, whilst it takes no longer than suturing a difficult perforation followed by a gastro-enterostomy, and is a far more satisfactory procedure. When should resection be performed? This depends on the question of time. When the patient is seen within six hours and his general condition is good he will stand the operation satisfactorily. The technique of the operation is just the same as that usually employed. The Polya operation is quicker than the Billroth II. The author further emphasizes the difficulties of diagnosis, specially when perforation is the first symptom of an ulcer. He advises a median incision and then proceeds according to the characters of the fluid found in the abdomen. With regard to drainage he advises this in late cases or where there is a large perforation, the drainage tube passing to the right iliac fossa. He concludes that in cases perforated under six hours they will stand a resection as well as if it was carried out under ordinary conditions.

104. Treatment of the Stiff Knee of Chronic Polyarthrititis.

T. NIELSEN (*Ugeskrift for Læger*, June 15th, 1922, p. 693) has come to the conclusion that the disorders of gait associated with chronic polyarthrititis are in the overwhelming majority of cases primarily due to disease of the knee and not of the hip. Attention should therefore be concentrated on the knee, and it is possible in many early cases to restore the functions of the knee to normal. It is of the greatest importance to encourage the patient to keep the limb completely extended at rest. To recommend pads and supports under the flexed knee in order to relieve pain is malpractice, although it is a course adopted even in large hospitals. In advanced cases the choice of treatment lies between resection of the knee-joint and forcible correction under a general anaesthetic, followed by immobilization for two to four weeks in plaster, and by weeks and even months of massage and muscular exercises. The first procedure is comparatively straightforward and simple; three cases of resection were a

great success in the author's hands. As for forcible correction he admits it is under a cloud, because without skilled and prolonged after-treatment it is liable to end in complete ankylosis. There is also the risk of serious injury and an exacerbation of the disease as a result of forcible correction. This fear is exaggerated, in the author's opinion, and he has six successful cases to enforce his advocacy of this method. He records, however, a case in which forcible correction was speedily followed by gangrene, entailing amputation at the knee.

OBSTETRICS AND GYNAECOLOGY.

105. The Ovarian Origin of Chlorosis.

G. ETIENNE (*Rev. méd. de l'Est*, May 15th, 1922, p. 329) observes that the discoveries of Brown-Séquard and his followers brought about a new conception of the nature of chlorosis and of its origin. It may be regarded as an auto-intoxication produced by a perversion of ovarian function. He classifies ovarian function as follows: (1) external secretion (ovulation); (2) elimination of toxic products at the menstrual period; (3) internal secretion, which plays an important part in the general nutrition. Chlorosis, therefore, is a toxic disturbance, amenorrhoea arresting the elimination of toxic products, while the failure of the internal secretion has profound effect on nutrition and the composition of the blood. He refers to recent researches on the internal secretion of the testicle and of the ovary and their effects on the general development of the individual, and states that in sixteen cases opotherapy has had striking results. In periods ranging from three to six weeks the red corpuscles have rapidly increased in number (in one case from 1,500,000 to 4,495,000). At the same time the number of abnormal corpuscles has diminished and the specific gravity of the urine has increased, with a proportionate increase in the excretion of urea and of phosphates. At the same time the patients' weight increased rapidly. The author and Prenaut suggest that the corpora lutea provide the ovarian internal secretion. He refers to the general cellular activity of puberty and suggests that if the ovaries become active at this period and menstruation is established, the first corpus luteum is formed, and its internal secretion plays its part in the general development. Quoting the analogous case of thyroid insufficiency and the production of myxoedema, the author suggests that ovarian insufficiency results in chlorosis. He believes that, prior to the development of ovarian activity, growth and development may be controlled by the thyroid and thymus, and that chlorosis may occur in the "physiological interregnum" resulting from too early retrogression of the thymus or retarded development of the ovary. The author considers that all the conditions to which chlorosis is usually ascribed—insanitary environment, deficient ventilation, improper food, etc.—act by arresting normal ovarian development. The author states that the administration of preparations of iron, in addition to that of ovarian extract, hastens the improvement in the condition of the blood.

106. "Uncontrollable" Vomiting in Pregnancy.

G. LEVEN (*Bull. Soc. de Ther.*, May 10th, 1922, p. 164), after treatment of a large number of cases of so-called "uncontrollable" vomiting in pregnancy, has come to the conclusion that the vomiting can very often be readily cured. In most cases it is due to one or more of the following causes: (1) dyspepsia created or aggravated by pregnancy, (2) gastric ptosis, (3) aerophagia. Cases due to the first cause consist of women whose meals have not been judiciously regulated; a cure can readily be effected in such cases by a proper arrangement of the diet. Cases due to the second cause consist of patients whose vomiting ceases spontaneously in the course of pregnancy when the uterus is large enough to raise the stomach; the application of a belt or a corset also produces a cure by the same mechanism. The third group consists of subjects of aerophagia which results from the salivation produced by pregnancy. In all these cases accurate diagnosis and suitable treatment lead to a rapid cure, provided hepatic or renal lesions are not present.

107. The Prevention of Puerperal Fever.

P. ZWEIFEL (*Deut. med. Woch.*, June 9th, 1922, p. 759) publishes tables showing how, at his hospital in Leipzig, the mortality from puerperal fever has varied in three different periods. After eliminating the cases which were already infected on admission to hospital, he finds that in the period 1887-1900 the mortality from puerperal fever was 0.0955; in the period 1901-1908 it was 0.1035; and in the period 1909-1917 it was only 0.0234. Since 1909 the practice has been adopted of examining the vaginal discharge of every pregnant woman

on admission to hospital. A thin, hollow speculum, through which 50 c.cm. of water are passed, is moved backwards and forwards in the vagina, and the returned fluid is then examined. If it is of a white, milky colour it is regarded as normal, but if it is yellow and flocculent the vagina is irrigated every day with 0.5 per cent. lactic acid. After this practice had been adopted for ten years, it was found that half the cases of severe puerperal fever occurred among women whose vaginal discharge was pathological during pregnancy and who had not undergone adequate prophylactic irrigation. On the other hand, 90 to 93 per cent. of the women who had been given prophylactic irrigations for at least ten days underwent a normal puerperium. In the cases with an abnormal vaginal discharge, which was often due to chronic gonorrhoea, the normal acidity was appreciably reduced. The author mentions two other precautions to which his reduced mortality from puerperal fever can be traced. The first was the isolation of all pregnant women with boils or other forms of suppuration anywhere in the body. The second was never to allow anyone to assist at a gynaecological operation who had, within the past eight days, been in contact with pus, whether gloves had been worn or not.

PATHOLOGY.

168. The Relation of the Fat-soluble Factor to Rickets and Growth in Pigs.

DEPRIVATION of vitamin A alone having been found insufficient to give rise to rickets in pigs, experiments have been performed by J. GOLDING, S. S. ZILVA, J. C. DRUMMOND, and K. H. COWARD (*Biochem. Journ.*, 1922, xvi, No. 3, p. 394) to ascertain whether this condition can be produced by the combined absence of vitamin A and of calcium from the dietary. Eight pigs from the same litter were divided into two groups; all were fed on the sow's milk, but, in addition, those in the second group received cod-liver oil and cream-rich in vitamin A—while two of the first group were given olive oil, which contains no vitamin A. After a period of fifty-three days the animals were weaned, and were then placed in four groups of two each. The first group received a diet devoid of vitamin A and of calcium; the second group, one devoid of vitamin A, but containing calcium; the third and fourth groups both received ample supplies of vitamin A, but, whereas the latter was given calcium as well, the former received none. During the following fifty-four days, though the intake in all the four groups was the same, there was a marked disparity in their weights. The two animals in Group I gained 42 lb., in Group II 49 lb., in Group III 63 lb., in Group IV 75 lb. After 145 days the experiment was terminated, and all the animals—with the exception of one of Group I, which had died in the meantime—were killed. The difference in rate of growth had been maintained throughout, those in Group IV being the heaviest and that in Group I the lightest of the animals. None of the pigs, however, developed rickets.

169. Rhabdomyoma of the Kidney.

PIANESE (*R. Accad. med. chir. di Napoli*, February 25th, 1922, and *Il Morgagni*, June 15th, 1922, p. 265) reports the findings at a necropsy held on a child aged 13 years. Two large tumours were found behind the peritoneum, filling the abdominal cavity and apparently attached to the kidneys. The tumour on the right side weighed 1,500 grams and measured 16 by 18 by 8½ cm.; that on the left weighed 780 grams and measured 16 by 10 by 5½ cm. On section the mass appeared to be made up of bundles of fibres like a fibroid, drish, of a greyish-white colour, with here and there some reddish-yellow patches. There was no naked-eye evidence of degeneration. It apparently arose from the kidney. It was made up of striped muscle fibres, very few blood vessels, connective tissue, and here and there a few isolated groups of cells which the author interpreted as undifferentiated cells from Balfour's intermediary cell group. The tumour was a pure rhabdomyoma of congenital origin, due to a defect in embryonic development.

170. Pulmonary Aspiration of Particulate Matter.

ACCORDING to H. J. CORPER (*Journ. Amer. Med. Assoc.*, June 17th, 1922, p. 1858), the distribution in the lung of particulate matter introduced into the respiratory passages depends to a considerable extent on the nature of the substrate in which it is suspended. Working with rabbits and dogs, he finds that inhaled smoke or soot is distributed fairly regularly throughout both lungs, where it is found chiefly in the air passages; very little appears to reach the actual alveoli. On the other hand, after aspiration of particulate matter suspended in fluids—such as India ink—it is found that the distribution of the foreign particles is markedly irregular; only certain

portions of the lung are affected, but in this the inhaled fluid is seen to have reached the alveoli themselves. Directing his attention to a closer study of this latter phenomenon, he shows the preponderating effect of posture in determining the actual location of the fluid in the lung. Thus, if India ink be dropped into a rabbit's nose while the animal is held in the vertical posture, it passes down to the lower lobes, while if it be introduced while the animal is kept in the horizontal position under ether anaesthesia it is subsequently found to be confined to the upper lobes. Moreover, if the rabbit be laid horizontally on one side, it is to the upper lobe of that side that the ink will flow. Using dogs, and replacing his ink by a saline suspension of dead tubercle bacilli, he was able to produce definite necrotic lesions in the upper lobe of either lung by simple instillation of the fluid into the dog's nose while the animal was kept on one or the other side in the horizontal position under ether anaesthesia. Whether posture is responsible to a noticeable degree for the transmission of tubercle bacilli from one part of the lung to another in the human subject it is difficult to say; but there is little or no doubt of the importance of the position of the patient during anaesthesia in determining the subsequent development of aspirative pneumonia.

171. The Enzymes of *Streptococcus haemolyticus*.

STEVENS and WEST (*Journ. Exper. Med.*, June, 1922) have succeeded in extracting three different enzymes from the haemolytic streptococcus—namely, a peptolytic, a saccharolytic, and a lipolytic one. The substances on which their activity was tested were peptone, cane sugar, and an ester of a fatty acid, such as ethyl butyrate or triacetin. Their most noticeable effect was found to occur in a slightly alkaline medium—somewhere between pH 7.0 and 8.0—corresponding closely with the reaction necessary for the optimum growth of streptococci. All three enzymes were highly susceptible to the influence of heat, acids, and antiseptics; a temperature of 60° C. for ten minutes was sufficient to destroy them completely. Minor differences in their resistance to acid were noticed. It is, of course, dangerous to infer from *in vitro* experiments to natural *in vivo* conditions, but there seems to be little doubt that, as in the case of the pneumococcus, the ferments secreted by streptococci are closely bound up with the pathological changes resulting from the invasion of the body with these organisms.

172. Bacteriostatic Power of Gentian Violet.

J. W. CHURCHMAN (*Johns Hopkins Hosp. Bull.*, June, 1922, p. 227) has studied the bacteriostatic and bactericidal power of gentian violet under varying temperature conditions. The large majority of Gram-positive bacteria do not survive exposure to gentian violet at room temperatures or in the ice-box, whereas about 90 per cent. of Gram-negative bacteria are completely unaffected by exposure to gentian violet for an hour under the same conditions. Heated to 50° C. gentian violet is actively bactericidal to all bacterial strains, an effect which the author thinks cannot be attributed to greater penetration at higher temperatures, or to the combined effect of heat and long exposure. Gentian violet is being used extensively as a bactericidal agent in purulent arthritis, empyema, and other suppurative conditions, but can only be successful after preliminary mechanical cleansing and lavage. Its effect is not so much bactericidal as bacteriostatic, for in empyema the dye does not sterilize the chest by killing the bacteria, but if a moderate quantity of the dye is left in the pleural cavity growth of organisms becomes very difficult if not impossible. Substances which hold bacteria in check without actually killing them may have real therapeutic value; but for this purpose gentian violet should be used as hot as possible to produce the maximum effect.

173. Relation of the Pituitary to other Endocrine Glands.

PETRAVALSKY (*Sbornik Lékařský*, xxi, 1-4, and *Zentralbl. f. Gynäk.*, April 22nd, 1922) compared the response shown by dogs, before and after extirpation of the hypophysis, to mechanical and electrical excitation of the muscle of the small intestine performed after subcutaneous injection of extracts of various endocrine glands. Extracts of thymus and intestine mucosa, which exerted on the intestinal musculature a well-marked spasmophilic effect lasting one or two hours, were found to exhibit diminished action in animals from which the hypophysis had been removed. In comparison with these extracts testicular and pancreatic extracts showed a less intense and less persistent spasmophilic action, which in the animals whose hypophysis had been excised was still less in the case of testicular extract, but somewhat greater in that of pancreatic extract. The spasmophilic action of thyroid extract was equally slight in normal dogs and in those whose hypophysis had been removed.

NINETIETH ANNUAL MEETING

OF THE

British Medical Association.

Held at Glasgow, July, 1922.

PROCEEDINGS OF SECTIONS.

SECTION OF MICROBIOLOGY (INCLUDING BACTERIOLOGY).

ROBERT MACNEIL BUCHANAN, M.B., F.R.F.P.S., President.

PRESIDENT'S OPENING REMARKS.

I ESTEEM it a great honour to have been asked to preside over this Section, and at the same time to have the privilege and pleasure of extending to you a cordial welcome. The city of Glasgow has many traditions for those of us who are its citizens, and we trust that our colleagues from a distance will each and all realize that one of the chief of these traditions is hospitality to sojourners within our gates.

In the directions for the conduct of our meetings the Council has laid a restraining hand on the presidents of Sections and asked them to forgo the delivery of a presidential address. It is an injunction in which I feel sure you will gladly acquiesce, and I will only refer to one or two points which I regard as of some interest in connexion with the origin of our Section and with the programme of its work.

In the thirty-four years since the British Medical Association held its annual conference in this city our conceptions of micro-organisms and the part they play in health and disease have undergone many developments. In that brief space of time microbiological science in its onward progress has exercised a profound influence in the realm of human, animal, and vegetable disease, explaining morbid processes, clarifying diagnosis, rationalizing treatment, and directing preventive measures; while in the realm of Nature it has revolutionized our ideas of the processes underlying growth and decay. Its place in our educational system has also become established, and each of our universities and medical and technical schools has a chair or lectureship devoted to its teaching, and almost all nations of the world have striven with each other in friendly rivalry in founding institutes devoted to its advancement by research.

Its early beginnings, which will be recalled by many present, may be likened to the waters that issued from under the threshold of the temple, and that swelled with almost incredible rapidity to a mighty river bearing a tide of healing, enlightenment, and new hope. In keeping with this general advance and broadening out of the science, the executive has seen fit to introduce for the first time in the history of the Association a Section of Microbiology (including Bacteriology), with the view of bringing together in helpful conference workers in allied fields of research. The processes of human disease, whether of bacterial or protozoal origin, receive helpful elucidation from the study of kindred processes in animals and plants, while our veterinary and botanical colleagues, on the other hand, derive benefit in their researches from the work done in the realm of human medicine. It is of very special interest to us to recall that we are thus realizing a suggestion made by Sir Clifford Allbutt in his address in medicine on the occasion of the Association's last visit to Glasgow a generation ago.

Having this object in view, the programme of our Section has been designed to embrace phases of microbiology showing the intimate relationship which exists between its various branches and how they hang together in evolving our common stock of knowledge. Investigations in the past have been mainly concerned with what may be termed for convenience the macro-microbic, while in the last few years attention has been largely focused on what may for contrast be designated the micro-microbic or filter-passing micro-organisms. It is not a little remarkable, and may be construed as a reflex of the scientific thought of the time, that three of the discussions in our programme deal more or less directly with the evidences of this realm of microbic life and activity.

We are privileged in having with us at this meeting pioneers in the field of bacteriolysis—Dr. Twort of the Brown Institution, and Dr. d'Herelle of the Pasteur Institute—and our indebtedness to them is very great, in that

they have accepted our invitation to discuss a problem weighted with so much interest and significance in the elucidation of the biology of bacteria, and one destined to give a new and more intimate meaning to the pathogenic action of individual species.

The bacteriology of influenza cannot fail to make a strong appeal to every one of us. It has been said that what is least understood is most feared, and such a truism may be very aptly applied to influenza. But I am able to assure you that much light will be let in upon this dark problem by the researches which Dr. Mervyn Gordon, of St. Bartholomew's Hospital, will lay before us.

On what may be called the comparative side of our programme Professor Blackman, of the Imperial College of Science and Technology, will deal with some similarities and dissimilarities between plant and animal diseases. The inclusion of this side of microbiology is a wholesome evidence of the broadening influences at work in bacteriology and parasitology, and which we confidently anticipate will illustrate the advantages of a closer collaboration between the microbiologists engaged in fields of work different, it may be, in materials, but identical in principles.

A subject of great interest to microbiologists—namely, the mutation of species—also finds a place in the programme on the day set apart for comparative work, and we are indebted to Dr. Brierley of Rothamsted for undertaking from his wide experience to open a discussion on this theme.

We will have presented to us interesting papers dealing with food poisoning and dysentery, by Drs. Wiseman and Robertson respectively, and with the intimate structure of the bacterial cell by Professor Ellis. An account of a brilliant piece of work done, one may say, in the African jungle, in elucidating the life-history of *Loa loa*, will be communicated by Dr. Andrew Connal.

The demonstrations connected with our Section have been arranged in the zoological laboratory adjoining, and I wish in your name to express our most cordial thanks to Professor Graham Kerr and Dr. Dunkerley for the excellent facilities they have provided for the display of the specimens.

DISCUSSION ON
THE BACTERIOPHAGE (BACTERIOLYSIN).

I.—THE NATURE OF BACTERIOPHAGE.

By Dr. F. d'HERELLE.

(From the Pasteur Institute, Paris.)

LET us record first, in a few words, the essential facts relating to the present discussion.

There exist in the intestinal contents of all living beings principles which have the property of dissolving certain bacteria. These principles pass porcelain filters; hence it is possible to separate them from intestinal bacteria.

Each filtering principle, isolated from intestinal contents of normal individuals, dissolves a certain number of bacterial species, belonging generally to the coli-typhoid-dysentery group. The action, therefore, of these principles is not strictly specific; but belongs, for a given filtrate, to a certain number of microbial species. In convalescents from an infectious disease a principle endowed with an energetic dissolving action on the bacterial species which causes the disease is always met with.

It is not only towards the intestinal bacteria that these lytic principles exist: for instance, one can isolate from the excreta of convalescents from bubonic plague a principle which dissolves *B. pestis*; the same phenomenon exists in various animal septicaemias.

I cannot enter here into an examination of all the facts relating to bacteriophage, facts most of which have been already confirmed by the investigations of other workers. But if the facts themselves have not been contested, it is not so in regard to the hypothesis which I have put forward to explain the nature of the principle which brings about the dissolution of bacteria.

A preliminary remark presents itself. Many authors who have formulated hypotheses as to the nature of the lytic principle have simply taken a particular fact supporting their own point of view and have neglected the whole assembly of experimental facts which renders such a thesis untenable, thereby forgetting that experiment is the final criterion of the truth of a theory. Let us try to resolve the question objectively.

The choice between the different hypotheses *a priori* possible to explain the origin of the lytic principle can only be made in accordance with a fundamental rule of logic—namely, in order that a hypothesis becomes admissible it is necessary that it should explain all the experimental facts and that it is not contradicted by any of them; further, in order that this admissible hypothesis may be considered as being in conformity with the nature of things, it must be proved that all the experimental facts cannot be explained if one abandons or modifies this hypothesis.

The bacteriolysis produced under the influence of the principle which we have named "bacteriophage" consists in a total dissolution of the microbial body; at the end of this action there remains no visible residue. A total dissolution of a microbial substance can only be due to a transformation or decomposition of the proteins of the microbe by proteolytic enzymes. Whence, it may be asked, come those proteolytic enzymes? Four hypotheses may be considered.

1. The enzymes may be derived from the animal organism which is attacked by the given bacteria. The enzymes would then be the result of a defensive reaction on the part of the organism.

This is the hypothesis of Kabeshima, Bordet and Cinea, and Ann Kuttner. Kabeshima² does not specify the particular tissue of the animal from which the enzymes originate; Bordet and Cinea³ indicate the leucocytes; Ann Kuttner⁴ incriminates any tissue.

2. The enzymes may come from intestinal bacteria as the result of a microbial antagonism. For instance, one knows the bacteriolytic action of filtrates of old cultures of *B. pyocyaneus*.

This is the hypothesis of Lisbonno et Carrère,⁵ for whom the lytic enzymes are secreted by intestinal bacilli such as *B. coli*, *B. proteus*, etc.

3. The enzymes may be secreted by the bacterium itself which undergoes the lysis. These enzymes would therefore be autolysins.

This is the hypothesis of Weinberg and Azuar.⁶ Under the action of a cause x the bacteria would acquire the property of secreting autolytic enzymes.

Bail⁷ had already indicated a similar origin, but his hypothesis was more complicated, and that in order to harmonize his conception with certain experimental facts to which we shall refer later. The bacteria undergoing lysis would become fragmented into filtrable corpuscles (the "splitters" hypothesis of Bail). These corpuscles would secrete enzymes capable of dissolving the bacteria from which they spring.

With the same view, Otto and Wiulder⁸ have put forward a hypothesis closely related to that of Bail, but for them the question resolved itself into one of bacterial albuminoid micelles, which do not reproduce themselves, but which secrete the lytic enzymes.

4. The enzymes may be secreted by an ultramicroscopic virus, which is a parasite of bacteria. This is the hypothesis by which I have held since my first publication.⁹

These four hypotheses cover all the possibilities. Let us now see which hypothesis conforms best with the experimental facts, at the same time eliminating those which fail to do so.

FIRST FACT: *The dissolution of bacteria under the influence of the bacteriophage principle takes place in series.*

That is to say, a filtrate containing the bacteriophage principle, when added to a culture in liquid medium of a bacterium towards which the principle manifests its lytic action, provokes the entire dissolution of the bacteria. A trace of the latter, inoculated into a second bacterial culture, leads to the latter in its turn undergoing total lysis. A trace of this second dissolved culture, inoculated into a third bacterial culture, produces the same phenomenon, and so on *ad infinitum*. After more than a thousand passages, the thousandth bacteriolysed culture contains a bacteriophage principle as active as, and generally much more active than, that of the primitive filtrate.

The phenomenon goes on in series in the same way, whether the culture is inoculated with the previously dissolved non-filtered culture, or with the dissolved culture filtered through a porcelain filter: the filtrate contains the bacteriophage principle as active as the lysed non-filtered culture.

A simple enzyme action would cease to show itself from the first tubes of the series, because of the greater and greater dilution of the enzyme solution in the course of the successive passages. One calculates easily that at the thousandth

passage (each passage being carried out on 10 c.cm. of a bacterial emulsion inoculated with 1/1000 c.cm. of the previously dissolved culture) the titre of the dilution in the thousandth tube of the series is given in cubic kilometres by the number 10³⁹⁸². To appreciate this incommensurable number in

interesting to note that, at the twenty-second passage or the drop of primitive filtrate introduced into the first tube of the series finds itself diluted in 10⁷⁰ cubic kilometres

liquid; such a cube of liquid is so great that a light would take one billion of years to cross one edge of it. It is impossible to conceive of an enzyme, contained in a single drop of primitive filtrate, still existing, without any diminution of its activity, after being diluted to this extent.

That the action may become manifest, each dilution must be allowed sufficient time (four to six hours) to permit development of the bacteriophage principle. On the contrary, when the dilution is utilized immediately, the bacteriophage action ceases about the fourth or fifth dilution.

These experiments establish clearly that a regeneration of the bacteriophage principle occurs at each passage. Consequently the lytic enzymes are produced by a living being which regenerates itself in the course of the successive passages.

It will be obvious, then, that this transmissibility in series eliminates hypotheses 1 and 2. The authors who have forwarded these hypotheses must admit that the principle derived from the organism which is attacked by parasites (hypothesis 1), or from the foreign bacteria (hypothesis 2) plays solely the rôle of a transformer—that is to say gives rise in the bacteria which undergo the transmissibility to a special state of "autolysability." We come then to the third hypothesis. Only Bordet and Cinea³ have attempted to give an explanation of this. For them the leucocytic principle would provoke in the bacteria "hereditary vitiation of nutritional nature." I must say that I do not understand how a filtered liquid can transmit hereditary property. Besides, the whole theory of Bordet and Cinea is based on an experience entitled "leucocytexudates," which I have elsewhere stated it is impossible to repeat—a statement which has not been challenged. Bordet.¹⁰ The result obtained by him in one experiment would appear to be purely accidental.¹¹

But it is to no purpose to discuss here, point by point, different theories; it is sufficient to show that they are contrary to the facts. Hypotheses 1 and 2 being eliminated, there only remain to consider hypotheses 3 and 4.

SECOND FACT: *The lytic enzymes emanate from material corpuscles which traverse filters; these corpuscles multiply in the course of the bacteriolysis.*

EXPERIMENT A.

In a well-developed bacterial culture, showing a marked turbidity, let us add a small quantity (say 1/10,000,000 c.cm.) of a filtrate containing the bacteriophage principle, shake, withdraw 1/20 c.cm. and spread it over the surface of an agar slope. Thus we spread over the agar a great number of bacteria and a very small quantity of bacteriophage principle. After incubation (eighteen to twenty-four hours at 37°) we note that the surface of the agar shows bacterial growth with a certain number of circular bare spaces here and there, where the agar presents no trace of growth. The vacant spaces once formed are unchangeable; they never spread and they are never invaded by the surrounding culture.

It is the presence of these inimitable bare spaces, which are perfectly circular, that characterizes what we have named "bacteriophage." Before concluding that any bacteriolytic phenomenon is bacteriophage, it becomes necessary to verify if it gives rise to such bare spaces on a bacterial culture. If not, the bacteriolysis is not of bacteriophage nature.

The number of spaces depends simply on the quantity of filtrate added to the bacterial culture. If into various bacterial emulsions we introduce variable quantities of filtrate, the number of bare spaces is strictly proportional to the quantity of filtrate added. On the other hand, the number of the bare spaces is independent of the number of bacteria contained in the medium; whether one introduces a given quantity of filtrate into a bacterial emulsion containing one hundred millions or ten billions of bacteria per centimetre, the number of bare spaces on the agar is practically always the same.

The phenomenon of these vacant spaces is only explicable on the supposition that the bacteriophage principle is of corpuscular nature. The following experiment gives the proof thereof.

EXPERIMENT B.

Given a filtrate containing the bacteriophagic principle, let us determine its force in the production of bare spaces.

It is well known that to determine the number of living bacteria contained in an emulsion agar plates are inoculated with a dilution of this emulsion; after incubation, the number of colonies which develop multiplied by the titre of the dilution gives the number of bacteria per cubic centimetre of the primitive emulsion. The enumeration of the bacteriophagic corpuscles contained in a filtrate is estimated in exactly the same way. But as the bacteriophage only grows at the expense of living bacteria, we must make the dilutions of the filtrate in a bacterial emulsion. For this we pipette over agar the bacterial emulsion containing a given quantity of filtrate; after incubation we obtain a bacterial layer strown with circular bare spaces, each of these spaces being a colony of bacteriophage issued from one corpuscle. The number of bare spaces multiplied by the titre of the dilution gives the number of ultramicroscopic bacteriophagic corpuscles contained in 1 c.cm. of the primitive filtrate.

This experiment shows that the behaviour of the bacteriophage is exactly the same as that of any ordinary microbe. But this last develops at the expense of the nutritive substances contained in the medium; the bacteriophage develops at the expense of the bacterial bodies which constitute its nutritive medium. The bare spaces represent places cleared up by the growth of the ultramicroscopic bacteriophagic corpuscles.

EXPERIMENT C.

Now dilute a filtrate so as to obtain a dilution such that 1 c.cm. contains one bacteriophagic corpuscle. Dilute this 1 c.cm. with 9 c.cm. of sterile water, and inoculate ten tubes of bacterial emulsion each with 1 c.cm. It will be obvious that only one of the ten tubes will contain the generator of a bare space; the nine others will not contain any. Place the ten tubes in the incubator at 37° for twenty-four to forty-eight hours; it will be seen that only one of the ten microbial emulsions shows bacteriolysis; the nine others will remain unchanged, the bacteria remain living, normal, and subculturable.

The lytic action, therefore, is complete when only one generator of a bare space is introduced into a bacterial emulsion; the action is *nil* in the contrary case. This experiment can only be explained on the supposition that the bacteriophagic principle, the source of the lytic enzymes, is a corpuscle; and that each corpuscle deposited on the agar in the midst of the bacteria gives rise to a colony of these ultramicroscopic corpuscles, such a colony being represented by a bare space.

EXPERIMENT D.

Inoculate a bacterial emulsion with a bacteriophagic filtrate of known corpuscular strength (that is, of known bare spaces forming force); make agar slopes every hour in the same way as in Experiment A. In this way, after six hours, we will have six agar slopes inoculated, and, on incubation, it will be seen that the number of bacteriophagic spaces (each bare space corresponding to a corpuscle) increases in proportion as the lytic action progresses in the emulsion. The maximum number of bare spaces is given when the lysis of the original emulsion is complete; at this moment there are no longer any living bacteria in the emulsion—it is a pure culture of the ultramicroscopic bacteriophagic corpuscles. The bacteriophagic power of such a lysed culture remains at its maximum level during many weeks—it is practically "fixed."

The foregoing experiments show that the lytic enzymes are originated by ultramicroscopic corpuscles which multiply and reproduce themselves. Hence those hypotheses explaining the phenomenon as being due to a soluble autolytic enzyme become eliminated.

Of all the hypotheses put forward, only that of Bail, and perhaps that of Otto and Winkler, could not be incompatible with these experiments, since they suppose that the olomont which secretes the lytic enzymes can be furnished by ultramicroscopic corpuscles, but derived from the bacteria. It is difficult to reconcile those hypotheses with the fact that the bacteriophagic action is not specific, and that the same strain of bacteriophage can dissolve bacteria of different species. Indeed, if one can understand how a principle originated by a species of bacteria can provoke the formation of a similar principle in a culture of the same bacterial species, it is hard to admit how this principle could provoke the formation of the bacteriophagic principle in a culture of a different bacterial species. Besides, these two hypotheses are rendered untenable by the following fact.

THIRD FACT: All bacteriophagic ultramicroscopic corpuscles, grown at the expense of any bacterial species, constitute one and the same antigen.

I have up to the present isolated various strains of bacteriophage active towards different bacteria: *B. typhosus*, *B. paratyphosus* A and B, *B. dysenteriae* (Shiga, Floxner,

Hiss), *B. coli*, *B. pestis*, *B. proteus*, *B. gallinarum*, bacteria of haemorrhagic septicaemias, staphylococcus, etc.

We have seen above what constitutes a culture of the ultramicroscopic bacteriophagic corpuscles. Inoculate an emulsion of *B. dysenteriae* with a filtrate containing an active bacteriophage towards this bacterium; after a few hours the medium becomes limpid, the bacilli are dissolved, and the bacteriophage corpuscles have multiplied; the culture of the bacteria has become a culture of antidysenteric bacteriophage. Similarly, a culture of *B. pestis* dissolved under the action of the bacteriophagic principle (isolated from the intestinal contents of a convalescent from bubonic plague) becomes a culture of antipestic bacteriophage. And so on for any other microbe.

One knows that the serum of a rabbit prepared by injections of *B. dysenteriae* contains an amboceptor towards *B. dysenteriae*, but does not contain any amboceptor towards any other bacteria—for example, *B. pestis*.

Now prepare a rabbit with a culture of *B. dysenteriae* dissolved by bacteriophagic action; one verifies that its serum does not contain any amboceptor towards normal *B. pestis*, but contains an amboceptor for *B. pestis* dissolved by the action of the bacteriophage. And this is true for no matter what bacterial species; the serum of an animal prepared by a culture of any bacterial species dissolved by bacteriophage contains an amboceptor which fixes itself on any other bacteriophage culture. Hence the amboceptor is specifically antibacteriophagic, and not antibacterial. Therefore the bacteriophage is an autonomous antigen, and consequently must be considered, in the present state of knowledge, as a definite ultramicroscopic virus constituted by corpuscles, such a virus being necessarily an ultramicrobe.

Only the hypothesis of a filterable micro-organism which is an obligatory parasite of bacteria is compatible with the foregoing facts. It now remains to show that this only admissible hypothesis is not contradicted by any experimental fact.

FOURTH FACT: The ultramicroscopic corpuscles possess a variable virulence.

We have seen that the above ultramicroscopic organism, which we have designated by the name of "bacteriophage," is constituted by living corpuscles which multiply and which it is possible to count. Now, experience shows that the lytic activity of these corpuscles varies from one strain to another. For instance, certain strains recently isolated from the organism are unable to provoke the dissolution of a bacterial emulsion, and no matter what number of corpuscles are inoculated into this bacterial emulsion, one can only perceive the presence of these bacteriophagic corpuscles by the production of pin-point bare spaces on agar. On the contrary, with very active strains giving on agar large bare spaces (4 to 5 mm. in diameter), the inoculation of one corpuscle is sufficient to provoke a total dissolution of all the bacteria contained in the emulsion. It is easy to prove that this difference in action is due to a difference in the multiplication of the corpuscles inoculated. In the case of feeble strains reproduction is slow; in the case of strong strains it is rapid. The active particle, therefore, is endowed with a variable virulence, the term "virulence" being taken in its real bacteriological sense of "vegetative power *in vivo*." To explain this fact one must consider the active corpuscle as a microbe, because only a microbe possesses a variable virulence from strain to strain. Moreover, an enzyme only acts by its quantity; a microbe by its virulence and its toxicity combined.

FIFTH FACT: By successive passages, it is possible to increase the virulence of a feeble strain of bacteriophage.

For instance, inoculate a feeble strain of bacteriophage into a culture of *B. typhosus*; filter the mixture after incubation; introduce a drop of this filtrate into a fresh culture of *B. typhosus*, which is filtered in turn, and so on for a few passages. The virulence is found to increase little by little, and after a certain number of passages the virulence becomes such that a trace of the filtrate is sufficient to provoke the total dissolution of a fresh emulsion of this bacillus. The technique of the exaltation of virulence is really the same as for any microbe: we exalt the virulence of a bacterium for a given animal by serial passages in this animal species; we exalt the virulence of the bacteriophage for a given bacterial species by serial passages in this bacterium. This fact is only compatible with the hypothesis that bacteriophage is a microbial parasite, since adaptation is the prerogative of living beings.

SIXTH FACT: Experience shows that bacteria attacked by bacteriophage do not remain passive; they defend themselves and are even capable, under certain conditions, of acquiring an immunity towards the parasite.

This defence of the bacteria manifests itself by a double mechanism: the bacteria surround themselves with a capsule, and secrete "aggressines" capable of paralysing the lytic enzymes of the bacteriophage. Only the hypothesis of bacteriophage being a parasite of bacteria conforms with those facts.

SEVENTH FACT: The behaviour of bacteriophage towards physical and chemical reagents is that of a living being, and does not agree with that of an enzyme.

The resistance of bacteriophage to the action of physical and chemical reagents is intermediate between that of the vegetative and the spore forms of ordinary bacteria. The resistance is less than that of certain ultramicrobes, notably that of the tobacco mosaic. It is destroyed at 74°-75° C., but ceases to develop at 43°. Between 43° and 74° it possesses no lytic action. As to the action of the antiseptics, the bacteriophage is killed after twenty-four hours' contact with a 1 per cent. solution of a neutral salt of quinine, after forty-eight hours' contact with 95 per cent. alcohol, and by eight days' contact with glycerin. The last-named liquid is precisely the medium employed for preserving indefinitely an enzyme in soluble form.

EIGHTH FACT: It is possible to extract the lytic enzymes free from the living bacteriophage micro-organism.

If to one part of a culture of bacteriophage is added nine parts of absolute alcohol and the mixture left forty-eight hours in contact, a precipitate is obtained which contains bacteriolytic enzymes, while the bacteriophagic germs are killed, which is proved by the failure of transmissibility in series of the phenomenon. One can only understand this fact on the supposition of an ultramicroscopic microbial parasite: the bacteria are dissolved by enzymes secreted by the living ultramicroscopic germs, hence the action in series. In the above experiment the ultramicroscopic germs are killed, while the enzymes already secreted are preserved intact; hence only a lytic action is obtained which is not transmissible in series.

NINTH FACT: Bacteriophage is capable of adaptation.

The bacteriophage is very sensitive to the action of acids—much more sensitive than ordinary microbes. It can be accustomed progressively to live in media containing quantities of an acid which would have been destructive before-hand. The same fact is observed with glycerin. Adaptation is a prerogative of living things.

TENTH FACT: The properties of bacteriophage are essentially variable.

It is impossible to isolate two strains of bacteriophage which are absolutely identical as to their range of action on different bacterial species, and as to their intensity of action towards each of these bacterial species. For a given strain of bacteriophage one can vary experimentally this intensity. Variability is an essential characteristic of life.

We have seen, first, that of all the possible hypotheses concerning the nature of the bacteriophage, the hypothesis of an ultramicroscopic parasite of bacteria is alone admissible. Moreover, we have just seen that this hypothesis is not contradicted by any of the facts of bacteriophagic phenomena; and, furthermore, all of the facts cannot be explained if this hypothesis is abandoned or modified. It follows logically, therefore, that such a hypothesis becomes a certitude.

Further, I would remark that I do not specify in any way the species to which the ultramicroscopic organism, which I have given the name of *Bacteriophagum intestinale*, belongs; the name simply recalls its characteristic property and the place where it was at first found. Is it a protozoon, a fungus, a bacterium? Does it belong to a kingdom which is neither the vegetable nor the animal—a still simpler form of life than any which we at present know? These are questions which cannot at present be answered. All that we know of it is that it is an ultramicroscopic organism, a filtrable being, parasite of bacteria, endowed with functions of assimilation

and reproduction—functions which characterize the living nature of the being which possesses these properties. That is all that experiment actually shows us.*

The foregoing discussion can only apply to the phenomenon of bacteriolysis in series presenting the special characters that I have indicated. This being so, a final question arises—that of the plurality of the serial phenomena.

In 1915 Twort¹² described a bacterial transformation taking place in series, under the influence of a principle which passes through porcelain filters. His researches have been made chiefly with a micrococcus isolated from vaccine. In addition he observed an identical phenomenon with two other bacteria—a large indeterminate bacillus, and a bacillus of the colityphoid group. Twort isolated the active principle in the following manner.

"Some interesting results, however, were obtained with cultivations from glycerinated calf vaccine. Inoculated agar tubes, after twenty-four hours at 37°, often showed watery-looking areas, and in cultures that grow micrococci it was found that some of these colonies could not be subcultured, but if kept became glassy and transparent. On examination of these glassy areas nothing but minute granules, staining reddish with Giemsa, could be seen."

The transforming principle is contained in this transparent material.

"The transparent material when diluted (one in a million) with water or saline was found to pass the finest porcelain filters with ease, and one drop of the filtrate, pipetted over an agar tube, was sufficient to make that tube unsuitable for the growth of the micrococci. That is, if the micrococci were inoculated down the tube as a streak, this would start to grow, but would soon become dotted with transparent points which would rapidly extend over the whole growth. If in an infected tube small areas of micrococci are left—and this usually happens when the micrococcus has grown well before being infected—these areas will start to grow again and extend over the transparent portion. . . ."

According to this description of Twort, it is not a question of a real bacterial dissolution, but a transformation of a normal culture on agar into a glassy and transparent one. This phenomenon is totally different from that produced by *Bacteriophagum intestinale*. Indeed, under the influence of this latter—no matter what bacterial species is dealt with, no matter what virulence, feeble or strong, of the strain of the bacteriophage, operating exactly in the same experimental conditions as Twort—in no circumstances does one observe the formation of transparent material or anything presenting such an appearance.

Pipette over an agar tube a drop of a diluted filtrate containing a bacteriophage active towards staphylococcus; then inoculate this tube as a streak with a pure culture of staphylococcus; after incubation we obtain a surface growth of the organism, which macroscopically, microscopically, and biologically is normal. This normal bacterial culture is strewn here and there with circular clear spaces; in the interior of these spaces the agar is bare, without any visible trace of any material. These bare spaces never spread over the surrounding culture, even after months in the incubator. Furthermore, they never become invaded by the surrounding bacterial culture: once formed, the bare spaces remain immutable. Confusion, therefore, between the phenomenon observed by Twort and the phenomenon provoked by the bacteriophage is in no way possible.

What is the nature of the principle which acts in the phenomenon of bacterial transformation observed by Twort? From a consideration of the observations made on this phenomenon, and in view of the fact that the lytic agent and the bacteria are destroyed at the same temperature, it is probable that it is derived from the bacterium itself, which is capable of splitting up into fragments. Twort himself favours this view, but further experiments will be necessary to settle this question.

This conclusion, however, does not detract in any way from the interest attaching to the important researches of Twort. One can already see that the phenomenon observed by this author may play an important rôle in the etiology of the so-called filtrable virus diseases, as he indeed seems to have foreseen. On the other hand, the bacteriophage undoubtedly plays a part in the defence of the organism in the course of infectious diseases, as I have shown elsewhere.

* I will mention, in passing, the hypothesis of Salimbeni: the enzymes would be secreted by a myxobacteria, microscopically and even bacteriologically visible, given filtrable spores. All the workers who have studied the question have failed to observe this would-be myxobacteria, which besides, according to the description of Salimbeni, presents a mycelium (?). That can only mean an impurity, as I have elsewhere pointed out.

From a survey of the results already arrived at in the domain of scientific investigation, it is easy to foresee that there exists a whole series of phenomena, quite unsuspected a few years ago, whose study should play a large part in the advance of scientific medicine.

II.—THE BACTERIOPHAGE: THE BREAKING DOWN OF BACTERIA BY ASSOCIATED FILTER-PASSING LYSINS.

By F. W. TWORT, M.R.C.S., L.R.C.P.

(From the Laboratories of the Brown Institution, London.)

This phenomenon of bacteriolysis, which in France has been called the "bacteriophage," consists, as you know, of a breaking down and dissolving up of bacteria by a filter-passing material which in certain circumstances may be associated with pure cultures. My first experiments were carried out at the Brown Institution during 1914 and 1915, for the Local Government Board, and the results were published in the *Lancet* (December 4th, 1915) under the title of "An investigation on the nature of ultramicroscopic viruses." The condition, in my opinion, is distinct from the various degenerative changes which have been so often described in bacterial cultures, and it will be unnecessary for me to consider in detail experiments on degenerative changes. It is also impossible in the time at my disposal to discuss every aspect of the subject; moreover, other speakers will no doubt deal with the many interesting experiments which they have carried out. In this paper I propose to give you as shortly as possible my original experiments as they were published in 1915, and I shall pass on to consider certain aspects of the subject which have since become points of controversy between different workers, and shall then deal shortly with certain more recent experiments which I have been doing on the biology of bacteria, as these may throw some light on the use of the lytic material.

When starting the research my object was to discover, if possible, the nature and life-history of the ultramicroscopic group of viruses. The experiments were carried out with these views in my mind: In the first place we do not know for certain the nature of an ultramicroscopic virus. It may be a minute bacterium that will grow only on living material, or it may be a tiny amoeba which, like ordinary amoebae, thrives on living bacteria or animal tissue. On the other hand, it must be remembered that if the living organic world has been built up slowly in accordance with the theories of evolution, then an amoeba and a bacterium must be recognized as highly developed organisms in comparison with much more primitive forms which once existed, and probably still exist, in nature. It is quite possible that an ultramicroscopic virus belongs somewhere in this vast field of life where the organization is lower than that of the bacterium or amoeba. It may be living protoplasm that forms no definite individuals, or an enzyme with power of growth.

In the first instance attempts were made to demonstrate the presence of non-pathogenic filter-passing viruses. As is well known, in the case of ordinary bacteria, for every pathogenic micro-organism discovered many non-pathogenic varieties of the same type have been found in nature, and it seems highly probable that the same rule will be found to hold good in the case of ultramicroscopic viruses. It is difficult, however, to obtain proof of their existence, as pathogenicity is the only definite evidence we have at the present time of the presence of an ultramicroscopic virus. On the other hand, it seems probable that if non-pathogenic varieties exist in nature these should be more easily cultivated than the pathogenic varieties.

The first experiments were carried out with such materials as soil, dung, grass, hay, straw, and with water from ponds. Cultivations were made on a large number of special media and under special conditions. Experiments were also carried out with pathological material obtained from distemper in dogs, from vaccinia, and from various other sources. The first results of interest were obtained with vaccinia. Inoculations were made on to ordinary agar tubes, and on to tubes of special egg media such as I used in my experiments for the cultivation of Johnes's bacillus and the lepra bacilli of man and of rats. It will be impossible to describe all these in detail, but the essential part of one series consists in the incorporation in the media of the dead bodies of certain acid-fast bacilli such as *Bacillus phlei*, which proved to be so successful in the cultivation of Johnes's bacillus. The egg media usually grew a number of colonies of micrococci and diptheroids, while the agar tubes grew only a few colonies of micrococci. In the case of the egg media it was noted that in a few days certain parts of the micrococcus growth sometimes became dull, and in appearance rather resembled bacterial growth in which amoebae were also growing. On the agar media the colonies of micrococci occasionally showed a translucent or transparent change, which started as more or less clear spots at the margins of the colonies. It was also found that some of these colonies could not be subcultured, but if kept the transparent change extended over most of the colony.

On examination of these glassy areas nothing but minute granules, staining reddish with Giemsa, could be seen. Further experiments showed that if a colony of the white micrococci that had started to become transparent was plated out instead of being subcultured as a streak, then the micrococci grow and a pure streak culture from certain of these colonies could be obtained. On the other hand, if the plate cultures (made by inoculating the condensation water of a series of tubes and floating this over the surface of the medium) were left, the colonies, especially in the first dilution, soon started to turn transparent, and the micrococci were replaced by fine granules. This notion, unlike an ordinary degenerative process, started from the edge of the colonies; and further experiments showed that when a pure culture of the white or the yellow micrococcus isolated from vaccinia is touched with a small portion of one of the glassy colonies the growth at the point touched soon starts to become transparent or glassy, sometimes killing out all the micrococci and replacing these by fine granules. Experiments showed that the action is more rapid and complete with vigorous growing young cultures than with old ones, and there is very little action on dead cultures or on young cultures that have been killed by heating to 60°C.

Anaerobiosis does not favour the action, although it appears best in tubes that are capped with gutta-percha tissue. The transparent growth when diluted (one in a million) with water or saline was found to pass the finest porcelain filters (Pasteur-Chamberland F. and B. and Doulton White) with ease, and one drop of the filtrate pipetted over an agar tube was sufficient to make that tube unsuitable for the growth of the micrococcus—that is, if the micrococcus was inoculated down the tube as a streak, this would start to grow, but would soon become dotted with transparent points which would rapidly extend over most of the growth. The number of points from which this starts depends upon the dilution of the transparent material, and in some cases it is so active that the growth is stopped and turned transparent almost directly it starts. This condition or disease of the micrococcus when transmitted to pure cultures of the micrococcus can be conveyed to fresh cultures for an indefinite number of generations; but the transparent material will not grow by itself on any medium.

If in an infected tube small areas of micrococci are left—and this usually happens when the micrococcus has grown well before becoming infected—these areas will start to grow again and extend over the transparent portions, which shows that the action of the transparent material is stopped or hindered in an overgrown tube; but it is not dead, for if a minute portion be transferred to another young culture of the micrococcus it soon starts to dissolve up the micrococci again. Although the transparent material shows no evidence of growth when placed on a fresh agar tube without micrococci, it will retain its power of activity for over six months. It also retains its activity when made into an emulsion and heated to 52°C, but when heated to 60°C. for an hour it appears to be destroyed. It has some action, but very much less on *Staphylococcus aureus* and *albus* isolated from boils of man, and it appears to have no action on members of the coli

group or on staphylococci, tubercle bacilli, yeasts, etc. The transparent material was inoculated into various animals, and was rubbed into the scratched skin of guinea-pigs, rabbits, a calf, a monkey, and a man, but all the results were negative.

When continuing my investigation of infantile diarrhoea and vomiting, for the Local Government Board in 1915, similar experiments were carried out with material obtained from the intestinal tract. After certain difficulties had been overcome it was found that in the upper third of the intestine, which contained numerous bacilli of the colon group, some larger forms were also present. In some cases these grew in far greater number than the ordinary types of bacteria, but this was only so when precautions were taken to eliminate the action of a dissolving substance which infected the colonies so rapidly that they were dissolved before attaining a size visible to the eye. Here, then, was a similar condition to that found in vaccinia, and the greatest difficulty was experienced in obtaining the bacilli free from the transparent dissolving material, so rapidly was the infection increased and carried from one colony to another. At first this bacillus was not believed to be a member of the dysentery-typhoid-coli group, but I have now no doubt that it was a special large form of a member of this group. Unfortunately I lost my cultures during the war before all the characters of the bacillus were completely worked out.

Similar though not such definite results were also obtained with a micrococcus and a member of the coli-typhoid group of bacilli which were obtained from the intestinal mucous membrane of a dog suffering from acute distemper, and I obtained some evidence that the difficulty often experienced in isolating certain known pathogenic micro-organisms might be due to the same cause. In my paper I also pointed out that results similar to those obtained with vaccinia and with bacilli from the intestinal tract would probably be obtained in cases of true dysentery; but I was unable at the time to investigate dysentery, as my scheme for research on this disease which was submitted to the War Office in 1914 was not accepted. Shortly after the publication of my work, however, I went to Salonica in charge of the base laboratory. While there in 1916 the subject was again discussed on several occasions with the English, French, and Canadian bacteriologists; but at the time the phenomenon was not accepted as one of much importance, and my fresh proposals for continuing the work on dysentery failed to meet with approval. As, however, I had predicted, a similar condition was later found to occur in cultures of true dysentery bacilli, particularly by Dr. d'Herelle, who carried out a series of important experiments on these bacilli. Dr. d'Herelle's published researches appear to me to confirm in the main my own results with micrococci and members of the coliform group of bacilli.

I will now pass on to consider the conclusions I drew from my experiments. In the case of vaccinia it is clear that the transparent material contains an enzyme, and this is destroyed on heating to 60° C. for one hour. It also increases in quantity when placed on an agar tube containing the micrococcus, and this can be carried on indefinitely from generation to generation. If it is part of the micrococcus it may be either a stage in its life history which will not grow on ordinary media but stimulates fresh cultures of the micrococcus to pass into the same stage, or an enzyme secreted by the micrococcus which leads to its own destruction and the production of more enzyme. The fact that the transparent portion cannot be grown except on the micrococcus makes it impossible to obtain any definite evidence on these points. There is this, however, against the idea of a separate form of life: if the white micrococcus is repeatedly plated out a colony from the last plates may give a good white growth for months when subcultured at intervals on fresh tubes; eventually, however, most pure strains show a transparent spot, and from this the transparent material can be obtained once again. Of course, it may be that the micrococcus was never quite free from the transparent material, or this may have passed through the cotton-wool plug and contaminated the micrococcus, but it seems much more probable that the material was produced by the micrococcus. Incidentally, this apparent spontaneous production of a self-destroying material which, when started, increases in quantity, may be of interest in connexion with cancers. In any case, whatever explanation is accepted, I do not think my experiments definitely disproved the possibility of its being an ultra-microscopic virus, because we do not know for certain the nature of such a virus. If the transparent portion were

a separate virus, it might be vaccinia, or it might be some contaminating non-pathogenic ultramicroscopic virus; for it is conceivable that whereas a non-pathogenic variety might grow on micrococci or bacilli, a pathogenic variety might grow only in the animal it infects. As the animal experiments were negative, there is no evidence that it is vaccinia, although such a virus might lose its virulence when grown outside the body. On the other hand, no evidence was obtained that it was a non-pathogenic variety. On the whole it seems probable, though by no means certain, that active lytic material is produced by the micrococcus, and since it leads to its own destruction and can be transmitted to fresh healthy cultures, it might almost be considered as an acute infectious disease of micrococci.

I have now described my original experiments and conclusions, and I will pass on to consider the views of other workers in this field. Where differences of opinion exist the controversy has centred chiefly round the experiments that have been carried out to determine the source and nature of the lytic material. I have already pointed out that when this material is diluted and filtered and pipetted on to a tube of medium just before inoculating the tube with the micro-organisms to be lysed, then the action starts at definite points throughout the growth. Dr. d'Herelle obtained a similar result in his experiments with dysentery bacilli, and he considers that a strong point in favour of the view that the lytic material is a separate living micro-organism. I cannot, however, for several reasons, agree that such experiments prove this. First, it is well known, notably in the case of certain starches, that the diastatic enzymes do not in every case dissolve up the grains evenly, but start at certain points, causing pitting and erosion of the grains; at the same time some grains are more susceptible to the enzyme than others. In this case no one has suggested that the unevenness of the action proves the diastatic enzyme to contain a living ultramicroscopic virus. I have noted also with bacteria that not only does the lytic agent attack some members of a culture before it attacks others, but individual members may be pitted and eroded, and particularly is this so with certain large forms of dysentery bacilli which I shall consider later. Again, it is well known in the case of a bacteria that certain members of a culture are more resistant to chemicals and to specific lysins produced in animals, and it may well be that the lytic action on the bacteria starts from a number of distinct points because these points happen to contain specially susceptible micro-organisms, and it is only when the action is started and the lytic substance increases in quantity and in concentration that the more resistant members become lysed.

Then there are the very interesting experiments of Professor Bordet and Dr. Ciuca. These workers found that when a lysin was produced by an animal against a coliform bacillus this lysin not only dissolved up fresh cultures of the coliform bacillus, but the lytic effect could be transmitted from the culture to culture. These results certainly do not favour the view that the lytic agent is a definite living micro-organism. Moreover, there are my own original experiments where, after obtaining normal growths of micrococci for a number of generations, eventually some fresh subcultures started to become lysed, apparently spontaneously. But these experiments appear to me to be evidence not only against the view that the lytic material is a definite living organism, but also against the view of Bordet and Ciuca that the lytic agent arises from an association of the bacterium with cells from the animal body. d'Herelle has also obtained the lytic agent by associating bacteria with filtrates of soil, etc., and I agree with him that these experiments do not support Bordet's view, although at the same time I do not think they support the view that the lytic agent is a definite living micro-organism. The apparent spontaneous production of the lytic agent in some of my pure cultures is, I think, evidence against both the views mentioned. It may, of course, be argued, as I mentioned at the time, that my cultures were never really quite free from the lytic agent, but if this view is accepted regarding my repeatedly plated cultures, then it is reasonable to suggest the same regarding the cultures used by d'Herelle and by Bordet.

Recent experiments, in fact, have in no way changed my views, and I repeat my original opinion regarding the lytic agent of the micrococcus—namely, that "the possibility of its being an ultramicroscopic virus has not been definitely disproved," and that "it seems probable, though by no means certain, that the active transparent material is produced by the micrococcus"; and I hold the same view regarding the

lytic agent which various workers and myself have found associated with the dysentery-typhoid-coli group of bacilli.

However, as I have already pointed out, it is just possible that an ultramicroscopic virus may be of the nature of an enzyme, and if so, the original source of such a virus might be the cell it infects: in remote ages possibly a normal enzyme which has gradually developed to take on a pathological action as it has passed through an infinite number of generations of cells; either bacterial, vegetable, or animal, according to its source, and which possesses the power either of directly increasing in quantity or of stimulating the cell to produce more pathological enzyme. On the other hand, it is conceivable that if this lytic agent be a pathological enzyme, it might bear the same relation to the normal enzyme that the cancer cell does to the normal cell. These possibilities may sound very improbable; but at the same time some such explanation would account for the extremely specific nature of many of the ultramicroscopic viruses, and it would certainly explain the absence of visibility and of growth on artificial media. After all, excluding such organisms as the lepto-spirillum of yellow fever, which probably belongs to an entirely different group, there are fundamental differences between the smallest micro-organisms known and the various ultramicroscopic viruses.

Cultivations of the minutest micro-organisms known show all the characteristics of ordinary bacteria. If these are obtained from the soil many of them grow well. On the other hand, if ultramicroscopic viruses are simply more minute members of the group of bacteria, there must be thousands of wild varieties in the soil, and yet no one has succeeded in obtaining a definite growth of a single variety on any solid medium. Minuteness of size might account for their being invisible, but it will not explain the absence of visible growth on artificial solid media. It is true that certain workers at one time claimed to have obtained growths of pathogenic varieties in Noguchi's medium, but in the absence of definite confirmation these experiments need not be considered here.

Professor Bordet and Dr. Cinca have carried out some most important experiments with the dysentery-typhoid-coli group of bacilli on the specificity of the lytic material, and have obtained results which indicate not only that the lytic agent can be made to break-down allied bacilli, but also that certain resisting and otherwise changed strains can be obtained. As I have already mentioned, my micrococci lysin had little effect on *Staphylococcus aureus*; but I did not carry out many experiments of this nature after obtaining the apparent spontaneous production of the lytic agent in my pure cultures of micrococci, as this result appeared to me to make it difficult to draw definite conclusions from such experiments. Many other workers, but particularly Dr. d'Herelle and Dr. André Gratia, have also carried out important experiments in this branch of the subject, but I must leave other speakers to deal with it, as it is impossible in the space at my disposal to do justice to their work.

There is, however, another aspect of the subject which I should like to mention. As is well known, in pure cultures of such bacilli as dysentery, typhoid, and coli, one sometimes meets with forms which are considerably larger and longer than the average bacillus, and these may be found in pathological material containing these bacilli, being not uncommon in urine in cases of cystitis. Hort and others have described these large forms in considerable detail.

In certain experiments dealing with the lytic material I observed these long forms in greater number than usual, and it was thought that they might in some way be connected with the lytic agent associated with this group of bacilli. There was also the possibility that they might be distinct but symbiotic bacilli growing only with the dysentery or other bacilli forming the culture; they might be mutations, or, again, they might be special forms with special work to do, like bees in a swarm, and, alone or in association with the lytic agent, might prove to be of importance in connexion with the pathogenicity of cultures and the production of immunity in the host.

The work was interrupted by the war, but eventually the results were published in the *British Journal of Experimental Medicine* (October, 1920), and I shall do no more now than consider their possible relation to the lytic agent. In the first place, it must be noted that these large forms occur much more frequently in pathological material than they do in cultures on artificial media. In cases of infantile diarrhoea and vomiting I have found them in large number associated with a lytic agent in the upper part of the intestinal tract,

and it is only after the action of the lytic agent is eliminated that they can be easily cultivated. The nature of the bacilli from such conditions is now being investigated.

Most of my experiments were carried out with the Shiga type of dysentery bacillus. The first point of importance to be noted is that the large or "special forms" occur in all pure cultures of bacilli belonging to the dysentery-typhoid-coli group, besides occurring in cultures of the influenza bacillus and other micro-organisms. Further, they are much more numerous in very young cultures than in older ones, and practically disappear in cultures that are twenty-four hours old. I observed also, in cultures that had been growing for six to twelve hours, that these "special forms" were often partially dissolved. From these early experiments I concluded that the bacilli normally produce "special forms," and that these, when presumably of no use to the bacterial community of a pure culture, are dissolved by a lytic agent which is also present, and that this lysin prevents the special forms from multiplying, and interferes with their isolation as growths free from the normal small bacilli. I found, however, two methods by which these "special forms" could be isolated. They may be obtained either by repeatedly plating out on litmus-maltose agar tubes, or by growing in an emulsion of dead coliform, typhoid, or some similar bacillus, and then plating out on the maltose agar medium. Three fairly distinct and stable types were isolated, but it will be unnecessary to consider these in detail. The chief points which I wish to bring to your notice are these: The large bacilli proved to be "special forms" of the bacterium from which they were obtained, and were easily agglutinated by the specific serums. I also obtained some evidence that they were more pathogenic when produced by the normal bacilli than after repeated multiplication by division. When isolated and grown they became more resistant to the lytic agent. In most of the cultures numerous free granules were present, while many of the bacilli contained similar looking granules in the fusiform and round swelling which they presented.

These researches seem to indicate another possible explanation of the lytic action of the substance under review. If this substance is, after all, not pathological to the bacterium, but is a normal product of its activity, then it must be produced for some special purpose which is advantageous to the life of that variety of bacterium. If the "special forms" of bacilli which are found in normal cultures and are so soon dissolved up are produced for the benefit of the bacterial community of a pure culture, then it may be that the lytic agent is formed for the purpose of carrying out this lytic action, and possibly setting free toxins contained in the special forms. Or it may be that it sets free "antitoxins," or substances that will neutralize the toxic substances of the host it infects, or such substances as are produced by other varieties of bacteria with which it struggles for existence when outside the animal body. Probably all bacteria produce substances of a toxic nature, but the possibility of their producing antibodies which will neutralize the toxins of other varieties is one that has interested me for some time. My experiments in this direction lead me to believe that this may be the case, but a research of this nature is rather difficult to carry out technically, and I shall do many more experiments before committing myself to this view. If, however, additional experiments should confirm my opinion, and if the special forms play some part in this process, one can quite understand that the special forms would be useless among the members of a pure culture growing on artificial media. In fact, they might be directly detrimental to the bacterial community, in that they would use up the food supply and overgrow the other bacilli which are necessary for a continuation of the life of that species or variety. In this case the lytic agent would perform a good purpose in getting rid of the useless special forms. It may be argued that this will not explain the lysis of the normal forms of bacilli, but then the conditions of cultivation on artificial media are not those of nature. In fact, in the process of evolution the bacterium did not develop its characters under the influence of cultivation in incubators, and an action that might be restrained to the limits of useful purposes in nature might very well extend beyond those limits under such an abnormal environment as that presented by an uncontaminated tube of agar.

Some of my views and the possibilities I have suggested are no doubt open to criticism, but I claim that the discovery of the filter-passing lytic agent in association with bacteria offers a large field for research, and I suggest that this field

has been further extended by the isolation of "special forms" of bacteria and by the possibility of demonstrating the production of bacterial antitoxins for the neutralization of toxins produced by other varieties of bacteria. Moreover, it must be remembered that all the vital processes of a bacterium have some relation to each other, and it is therefore necessary to study these problems together, or the true significance of any one may not be fully appreciated.

III.—CONCERNING THE THEORIES OF THE SO-CALLED "BACTERIOPHAGE."

By J. BORDET, M.D.,

Director of the Pasteur Institute, Brussels.

[The following explanatory statement was read by Dr. Gratia for Professor Bordet.]

Through Dr. Gratia I obtained access to the paper Dr. d'Herelle intends to present on the lytic phenomenon due to the so-called "bacteriophage." I was not a little surprised to find that Dr. d'Herelle in this paper attributes to my co-worker, Dr. Ciuca, and to myself, as regards the intimate nature of this phenomenon, an opinion which is wholly different from what we felt entitled to uphold from the very beginning of our studies on the subject.¹ Dr. d'Herelle quotes our names next to Kabeshima's, and enlists us among the authors who assume that the lytic principle is a leucocytic secretion. In fact, this view seems to us altogether untenable, and is almost the reverse of the opinion we have constantly emphasized.

I think we were first to advocate the view that the lytic inciplo is produced by the microbe itself which shows the same—in other words, that the transmissible lysis is in reality autolysis betraying a nutritive vitiation primarily started by external influences, an example of which may be the contact with a leucocytic exudate. No doubt it would be quite unnecessary to translate literally the many passages of our papers where this assumption is advocated. Some lines, however, may be quoted:

"External influences such as that of a leucocytic exudate modify a bacterium, inducing the latter to elaborate a lytic substance capable of diffusing itself and bringing about the same autolytic phenomenon through successive cultures. When the autolytic process occurs a large number of the microbes present may perish, at some of them, being more resistant, are, during a certain length of time, still capable of reproduction in spite of their producing the active principle, thus imparting to new cultures of the same microbe the same autolytic tendency."

In another paper we add:

"According to d'Herelle, the lysis is due to a living being, to filtering virus. We, on the contrary, believe that the lytic principle originates from the bacteria themselves, which, when touched by this active substance, are capable of regenerating it, the factor responsible for the phenomenon being thus unceasingly reproduced—on the condition, however, that the bacteria be still living and provided with the alimentary substances necessary to their growth."

I wonder how Dr. d'Herelle could possibly give such an erroneous account of our work as in his paper. The many authors who have written on the subject did not, like Dr. d'Herelle, misinterpret a theory which we have so often and so distinctly outlined and explained. I shall allow myself to quote, for instance, the paper recently published by Dr. Bruyogno,² who writes:

"According to Bordet and Ciuca, the microbes undergo—through the agency of a leucocytic exudate—a modification by which they are henceforth capable of elaborating an autolytic principle, this property being further transmitted to the following generations by the germs which were sufficiently resistant, and thus could multiply. This interesting view permits the understanding of the fact that the lytic principle is only regenerated when the bacteria are living, since the theory asserts that this principle is produced by the bacteria themselves."

I think there is no need to dwell longer on the subject, but one must agree that I could not refrain from correcting d'Herelle as regards our views, nor from presenting them again as they are expressed in all of our papers. The mere titles of these are clear enough; we always designate the phenomenon under the name of "the microbial transmissible autolysis."

IV.—ANDRÉ GRATIA, M.D.,

Pasteur Institute, Brussels.

1. The Twort phenomenon and the d'Herelle phenomenon are identical. They are two different aspects of one and the same phenomenon: the transmissible lysis of bacteria.

When the "dissolving material" of Twort found in diseased agar cultures of micrococci obtained from vaccinia lymph transplanted into a young broth culture of staphylococcus a dissolution of the latter occurs, and the filtrate of the dissolved culture exhibits all the characteristics of a typical staphylococcus bacteriophage according to the definition of d'Herelle.

On the other hand, typical staphylococcus bacteriophage could be obtained also by other means—namely, by the leucocytic exudate technique of Bordet and Ciuca, or by the puncture of a subcutaneous abscess. When small amounts of this staphylococcus lytic agent are introduced in melted agar which is afterwards slanted and seeded with sensitive staphylococci a culture results, apparently normal at the beginning, but which, a little later, turns into the typical glassy transparent material of Twort. In other words, the Twort phenomenon leads to the d'Herelle phenomenon, and inversely, the d'Herelle phenomenon leads to the Twort phenomenon.

2. There are no unquestionable proofs that the bacteriophage is a living organism.

The assumption of the bacteriophage being a filtrable virus for bacteria was suggested by two main facts: (a) The power of reproduction possessed by the lytic agent, and (b) the localization of the lysis to certain round spots of clarification when a very diluted lytic agent is poured over the surface of an agar culture of sensitive bacteria. Although easily explained by the virus theory, yet both facts are not unquestionable proofs of the living nature of the bacteriophage because they are by no means exclusive features of living beings.

Fire is not living, and yet fire is endowed with power of reproduction. When once lighted, thanks to an initial impulsion such as an electric spark or the more striking of a match, it can be indefinitely reproduced if fuel is provided. A still more striking, because more biological, example is found in blood coagulation. Suppose a series of test tubes containing a stable plasma—bird's plasma, for instance—which will remain indefinitely fluid. To the first tube we add just a few cubic centimetres of distilled water. As a result, that initial thromboplastic action, which does not need to be repeated in the future, thrombin suddenly appears in the first tube and the plasma clots. If a few drops of the exudate serum in the first tube are pipetted off and poured in the next tube, this second tube clots, in its turn, with a new regeneration of thrombin, which, transformed in the third tube, brings about the coagulation of that tube with again a new production of thrombin, and so on indefinitely. In this way we realize the transmissible coagulation of blood in series, with the continuous regeneration of thrombin, and thrombin is not a living being.

The localization of the lytic action of diluted bacteriophage can be explained by the hypothesis of a chemical substance as well. It must be kept in mind that a culture is not a homogeneous whole, but made up of organisms showing a variety of qualitative and quantitative individual differences—that is, as far as their susceptibility to the lytic agent is concerned. When a very concentrated lytic agent is poured over the surface of an agar culture an almost complete dissolution occurs, with the exception of just a few organisms resistant enough to overwhelm the strong action of the concentrated lytic agent. On the other hand, when a dilute lytic agent is used only the few extremely sensitive bacteria will be influenced, and each of them becomes a centre of regeneration of the lytic agent, which, diffusing evenly in every direction, produces perfectly round spots of clarification: very often surrounded by a kind of halo of diffusion. Between these two extreme conditions all kinds of intermediate degrees exist. Further, any substance, living or not, is composed of particles, molecules, atoms, or ions. When we pour out a glass of soda water, there appear on the wall of the glass small round bubbles of gas, the size of which increase exactly as the so-called colonies of bacteriophage, and yet gas is not a virus.

3. The idea of the bacteriophage being a product of bacterial activity is suggested by the close parallelism existing between the regeneration of the lytic agent on the one hand, and the activity of growth of the bacteria on the other hand.

No regrowth occurs in dead cultures, nor in living cultures when put in such conditions that they cannot grow—in saline emulsions of bacteria, for instance, or at low temperature. A slight lysis, with but a small regeneration of lytic agent, is induced in the slow-growing culture of *B. coli* in a synthetic medium. On the contrary, an abundant regeneration occurs in a fast-growing culture in broth. A recently seeded broth culture to which is added just a trace of lytic agent will not be inhibited; but a few hours later, at the very moment the culture reaches its acme of growth, a rapid dissolution occurs with an abundant regeneration of lytic agent.

4. The conception of the bacteriophage being a chemical substance is favoured by the chemical-like affinity existing between a given lytic agent and the corresponding susceptible strain.

I first observed that small amounts of lytic agents lose a certain part of their activity when put together with too thick emulsions of sensitive bacteria. Bordet, with a different technique, could even obtain the complete disappearance of traces of lytic agent in the same condition. Still more convincing are the results of Yaumain and of Da Costa, who observed the absorption of relatively important amount of lytic agent by dead emulsions of the corresponding sensitive bacteria. This specific affinity which is the necessary condition for a lytic agent for inducing the dissolution of a given bacterium is not favourable to the virus theory, because we question how a virus could be definitely fixed by dead bacilli, which, however, it is unable to attack.

5. The bacteriophage is not one and the same antigen. Several lytic agents showing antigenic specificity must be considered.

The *coli* lytic agent can be completely neutralized by proper amounts of corresponding *coli* antilytic serum, but is not at all affected by staphylococcus antilytic serum, which, on the other hand, is only able to neutralize staphylococcus lytic agent and not *coli* lytic agent. This neutralization reaction is thus specific, and demonstrates the plurality of the bacteriophage.

The non-specific results obtained with the alexin fixation reaction and advocated by d'Herelle in favour of the unity of the bacteriophage, are of no value, because they are vitiated, as can be easily demonstrated, by the presence in the bacteriophage of bacterial dissolution products which have lost their specificity and play therefore the rôle of common antigen between different lytic agents.

V.—J. C. G. LEDINGHAM, D.Sc., M.B., F.R.S.,

Chief Bacteriologist, Lister Institute, London.

THE problem which has exercised the minds of all who have personally investigated the subject has been to elaborate some theory which will adequately explain the facts. Dr. d'Herelle maintains unaltered his originally expressed view that the phenomenon of transmissible lytic effect is fully explained by assuming that a living ultramicroscopic virus parasitizes and brings to solution the particular organisms with which it has most affinity, and that the apparent increase of lytic effect in passage is due simply to growth of the alleged live virus. Even if, as d'Herelle claims, his premises warrant the conclusion to which he arrives, I should still hesitate in accepting it. I should desire to be satisfied that the alleged cause was a *vera causa* in the sense of the old logicians—that, in fact, it was a cause which did not tax too severely one's sense of the naturalness or likelihood of things. But are the premises so indubitably established? Is no other general explanation possible? The investigations so far undertaken display an extraordinary variety of experiment, sometimes yielding uniform, sometimes highly conflicting, results, and I feel strongly that, throughout, there has been little attempt to study the phenomena on quantitative lines, with a view to eliminating or evaluating the various known possible factors and agencies that may, either in conjunction or separately, give rise to the end-result. It is possible, however, from the sheer mass of data recorded to take the following facts as presumably established.

1. That certain organisms, particularly those of the intestinal group, submit readily to lysis under the influence of a variety of primary stimuli. These may be filtered faecal extracts from healthy or diseased persons, or they may be extracts of normal tissues or body secretions. Filtrates of these organisms so dissolved are able to carry on the process.

2. That some strains of these same organisms are naturally resistant to these same stimuli.

3. That some strains of these same organisms show lytic changes normally. I attach great importance to this fact. Dr. Lepper, at the Lister Institute, recovered from the urine of a case of pyelitis a coliform strain which behaves in culture as if it were a mixture of bacilli and "bacteriophage." Its growth curve in broth showed repeated depressions, which can be explained only by antilytic effects. On agar the characteristic patchy growth of irregular nibbled colonies appears.

4. That the stimulus if not too strong causes a dissociation of the strain acted upon, into resistant and non-resistant types.

5. That potent lytic extracts can be prepared from the organisms themselves during artificial growth, the process being apparently facilitated by repeated filtration of the growth and reinoculation of the filtrate with the organism concerned.

6. That potent lytic extracts can be obtained from the filtered growth of organisms growing symbiotically.

In whatever way the initial stimulus is obtained the transmission in series can, in my view, be explained only on the assumption that potent antilytic ferments discharged from the lysed organisms are able to initiate similar effects in passage. My own work has been concerned with filtrates of *B. pyocyaneus*, which are known to dissolve readily organisms like *B. anthracis* and *V. cholerae*, but which may fail entirely with certain other species. I have not yet been able to show definite carry-over by ferments from organisms so dissolved, but it is probable that the proper conditions have not been secured. Malfitano, twenty years ago, showed that *B. anthracis* suspended in distilled water liberated antilytic ferments, and he pointed out what is of extreme importance in securing the carrying over—namely, that the organism must be so killed that the ferments discharged are not injured. It is important, therefore, if one wishes to eliminate superfluous factors, to seize on the simplest exposition of the experiment. The simplest exposition so far is, I take it, that in which the organism's own extract can initiate the "bacteriophagic" action. That extracts of organisms may exhibit lytic powers is, of course, no new observation, and it is helpful now to bring these older observations into line with new experiment. The second simple procedure which yields, apparently in a remarkably short time (in a matter of hours, in fact), a potent lytic stimulus is the inoculation of organisms into the circulation of an animal and the demonstration of "bacteriophagic" powers in the serum drawn a few hours later. If the results on this point are confirmed, we seem to have the phenomenon reduced to the simplest form, and it is remarkable that it fits in with certain phenomena the explanation of which has long puzzled us. I may refer, for example, to the extraordinarily rapid development of immunity to plague after inoculation of highly purified plague extracts in rats (Rowland), and to the remarkable though temporary increase of normal antibody which rapidly follows the injection into animals of autolysed bacterial bodies or refined substances like nuclein. I feel that here we have a promising link between "bacteriophage" work and certain previously recorded phenomena.

It is difficult at this stage to evaluate the alleged therapeutic results of these "bacteriophages." There is no doubt, however, that just as *pyocyaneus* filtrates can abort an anthrax infection in rabbits when injected simultaneously with the organism, so a similar local action may well be expected with the filtrates of d'Herelle. It seems to me unlikely, however, that much is to be expected from their therapeutic use in virulent infections in highly susceptible animals. I am not greatly impressed with the evidence of specificity of these "bacteriophages" based on complement fixation tests with immune serum. I take it that, from the work of Otto, Munter, and Winkler, the immune serums obtained by immunization with bacteriophage filtrates is essentially of the same kind, if not of the same order, as those obtained by immunization with the raw organism or its autolysate. Any alleged differences would seem to be due simply to the fact that the bacteriophage filtrates are in a highly refined colloidal state. To this high refinement, which is facilitated by repeated filtration and reinoculations, Otto, Munter, and Winkler attribute the potency of their products as compared with supernatants obtained by the centrifuge only. Just as the anaphylatoxin effect was whittled down to an interaction between two colloids, so I would urge for the investigation by quantitative

methods of the simplest form in which the phenomenon can be elicited. The two main factors in the problem are, to my mind: (1) the variability of bacteria in the matter of susceptibility to lytic change, and (2) the lytic action of extremely finely divided colloidal bacterial protein on susceptible bacteria. From such interaction would result the liberation of autolytic ferments capable of repeating the process in series.

VI.—J. W. McLEOD, O.B.E., M.B.,

Professor of Bacteriology, Leeds.

Dr. d'HERELLE in his opening address brought forward some arguments to show that the phenomena which he has described are distinct from those previously described by Dr. Twort. This may be so in a limited sense, and the development of glassy areas in an opaque culture of a micrococcus on the one hand and the transmissible lysis of emulsions of Shiga bacilli on the other, appear to be new and important demonstrations of bacteriolysis by substances derived from the bacteria themselves, or closely associated with them, and in this respect unique phenomena.

The observations, however, on which d'Herelle based his case for proving the existence of an invisible, bacterium parasitic of the species under investigation—that is to say, the development of bare spaces amidst the growth on an agar slope when the latter was inoculated from a bacterial emulsion to which a small amount of a bacteriolytic filtrate has been added—do not appear to differ essentially from the older results of Eijkman on auto- and hetero-inhibitions in bacterial cultures. The chief points brought out by this worker were:

1. That most, if not all, bacteria produce in the course of their growth substances inhibitory of that growth.
2. That in the case of some bacteria the substances produced act as powerfully, or more so, on other bacterial species.
3. That these substances are thermolabile.

I have been working at intervals since 1918 on this subject of the production of bacteriocidal substances by bacteria, and I have come to the conclusion that they are diverse. In the case of the thermolabile bacteriocidal substances produced by pneumococci and many streptococci (studied in collaboration with Mr. Govouloek and Dr. Gordon¹), which at the outset were thought to be of complex constitution and protein in nature, the quite unexpected conclusion has been reached that the substance responsible is hydrogen peroxide.

The substances inhibiting growth produced by the coliform group of bacteria are certainly different. It is not unreasonable, however, to consider the phenomena brought forward by Mr. Twort and Dr. d'Herelle as special types of the general class of phenomena first carefully investigated by Eijkman, and I believe that a more rapid elucidation of them is likely to be found if they are considered in the light of that worker's results.

Certain observations made in the winter of 1917-18—in some of which I was associated with Dr. A. G. Ritchie—may be of interest in this discussion. These observations dealt with the inhibition of the growth of *B. coli* by filtrates of dysentery cultures in fluid media, and vice versa. The object of the observations was to produce if possible a culture medium exhausted for the growth of *B. coli* but still capable of growing dysentery bacilli. In the course of this investigation it was found that all the coliform bacilli tested grew well in 20 to 25 per cent. dilutions of most samples of Allon and Hanbury's trypsin. The activity of the trypsin was confirmed in each sample. It was observed, however, on one or two occasions that the strain of Shiga's bacillus used grew well, producing frank turbidity in the first twenty-four hours of incubation, but that this turbidity would clear up on further incubation. Another observation was that such media and also tryptic digests of coagulated serums, etc., which were sterile but not inactivated, were those in which *B. coli* most readily produced substances inhibitory to its own growth. Filtrates from such cultures were about equally inhibitory to the growth of Shiga, Flexner or Y dysentery strains, however. With filtrates from growths of dysentery bacilli in such media, however, the results were much more specific—that is, filtrates from cultures of Shiga's bacillus inhibited the growth of Shiga bacilli, but not that of *B. coli* or Flexner's bacillus. Corresponding results were obtained with the other dysentery strains.

An attempt to determine the nature of the inhibitory substance in filtrates of *B. coli* cultures showed that it was

not thermolabile but that it was readily thrown out of action by dilution or by addition of alkali. It did not, however, appear to be a matter of degree of acidity, since artificial acidification of culture media to a higher degree did not sensibly interfere with the growth of the bacilli concerned. There is evidence here of the rapid production in suitable fluid media of substances inhibitory to the growth of Shiga bacilli, and it may be that these bacilli when killed by agent which does not interfere with their internal enzyme or which may possibly stimulate these, does undergo a rapid autolysis, just as dead tissues in the animal body do. On the other hand, the bacteriocidal substances demonstrated by Eijkman's technique or modifications of it in ordinary culture media appear to be thermolabile, being at least partly destroyed by short periods of heating at 65° C. in the case of *B. coli* or the dysentery bacilli.

Of all the bacteria which have been investigated Eijkman's technique Shiga's bacillus is the one most sensitive in its growth to inhibition by many varieties of bacteria.

Of course, it must be admitted that until a more complete explanation of these phenomena has been provided d'Herelle's hypothesis cannot be finally rejected. Inasmuch, however, as he has claimed for his micro-organism two characteristics which are without parallel in bacteriological observation: (1) a heat resistance on the part of the bacteriophage greater than that demonstrated in connexion with any of the ultramicroscopic virus occurring in the animal body, (2) an organism which grows actively in fluid media with production of turbidity—I find it impossible to accept the theory without much more satisfactory proofs than that which he has advanced.

DISCUSSION.

Dr. FLEMING (London) showed some agar plates illustrating the rapid bacteriolysis produced by egg albumen and antiseptics, such as tars. The chief characteristics of the reactions was the rapidity with which they took place, a bacterial growth being quickly clarified by the diffusion of the lytic agent.

Dr. A. W. M. ELLIS (London) said: I desire at the outset to associate myself with the remarks of Dr. Gratia and Ledingham, who have already covered most of the ground which I had planned to speak. I wish in particular to emphasize Dr. Ledingham's remarks on the necessity of quantitative measurements in working with this phenomenon. In all work I have employed quantitative methods, the result being investigation in serial dilutions, the following table being set up, the dilution in each being ten times that in preceding:

-1	-2	-3	-4	-5	-6	-7	-8	-9
10	10	10	10	10	10	10	10	10

With an active filtrate complete lysis will always occur up to 10⁻⁸—that is, to a dilution of 1 in 100,000,000. In this I have investigated the effect of variations in temperature, hydrogen ion concentration, suspending fluid employed, and upon the reaction; the results will shortly be published in detail.

To-day there are two points to which I would particularly like to draw attention, because I feel that in the solution of their mechanism lies in all probability the key to the nature of the processes involved in the phenomenon. The first is the occurrence of a zone phenomenon, so familiar to work with colloidal reactions, and especially familiar in the case of immunity reactions, such as complement fixation and precipitation. That is, that the occurrence of lysis is restricted to a certain zone in the scale of dilutions, and that if higher concentrations of lysin are employed lysis frequently fails. Thus, in the above-mentioned series of dilutions it is unusual to find a failure of lysis in the tubes containing 10⁻¹ or 10⁻², although lysis is complete below this down to 10⁻⁸.

The other point is the question of the effect of dispersion of the lysate—that is, the bacterial bodies in the emulsion used. If one takes 10 c.c. of thick emulsion of Shiga, divides it into equal parts, and adds to each an equal quantity of lysin, and then dilutes one of these equal parts 1,000 c.c. of broth, complete lysis will occur in the diluted one, none in the undiluted—that is, the occurrence of lysis

is dependent upon the degree of dispersion of the bacterial suspension.

In these two reactions we see phenomena which remind us at once of the behaviour of colloidal solutions, and it is in the realm of physical chemistry that we should look for a solution of this problem.

To d'Herelle's contention that a living virus is responsible I find myself in complete opposition. Of the arguments produced by d'Herelle in support of his theory, three seem to me particularly pertinent, and I would like for a moment to refer to them in more detail.

1. Colony formation. This, it seems, is readily explainable on the assumption that these points represent the sites of occurrence of highly sensitive organisms. We know the great variation in sensitiveness to lysis that occurs among the organisms of any given culture.

2. The isolation of a single individual. This merely means that the lysis is capable of division into a terminal unit, and that such a terminal unit—that is, single molecule or what not—is capable of initiating the reaction. It is no argument for the living nature of the lytic agent.

3. The effect of alcohol. d'Herelle has claimed that he can by the use of alcohol obtain the lytic products of the lytic agent free from the latter. That is, that after saturation of the lytic filtrate with alcohol he obtains a substance which is lytic, but capable of transmission, not lytic in series. If this is true it is of first rate importance. I have repeated the experiment many times, but always unsuccessfully. If lysis occurs it can always be transmitted in series.

As to the rôle of the lysis in recovery from disease I can only say in conclusion that my experiments have given entirely negative results, and that my own feeling is that it plays no part. My experiments have been with Gaertner's bacillus and infections in mice and have shown only an aggressive action for the lytic filtrate—that is, controls fed with "bacteriophage" prior to infection have died more rapidly than normal controls.

Professor DAVID ELLIS (Glasgow) said: When sulphur bacteria have used up all the food supply contained in the cells in the form of sulphur they eventually come to rest, and each filament breaks up into compartments by means of transverse walls. Each cell then begins to swell up and assumes a spherical form and literally disappears. Certain iron bacteria, such as *Crenothrix polyspora*, sometimes multiply with extraordinary rapidity and the whole organism breaks up into minute specks. The circumstantial evidence is very strong that these elements disappear completely.

The PRESIDENT (Dr. Buchanan) summed up the discussion and emphasized the necessity of collaboration between the various departments of biological science in the elucidation of this problem.

Replies.

In his reply Dr. Twort said that there were one or two points to which he would like very briefly to reply. It had been suggested that the bacteriolysis or bacteriophage would only act on very dilute emulsions of bacilli, and not on a thick growth, as is the case with the lysozyme of Fleming. This, however, was not altogether correct, for if a very active bacteriolysin which might be obtained from cocci from vaccinia was transplanted on to the edge of a young vigorous growth of cocci or mixed with the cocci scraped from the surface and transplanted to a fresh tube, then lysis would take place. A suggestion had also been made that the phenomenon of bacteriolysis might possibly be of the nature of a degenerative process and be somewhat similar to the swelling and degeneration observed with the sulphur bacteria. He did not, however, think this was probable, for it was important to remember that the bacteriolytic action was most marked on very young, vigorous growing cultures on good media, which was not what one would expect if it were a degenerative process. Dr. d'Herelle had pointed out what he believed to be differences in the nature of the substances as described by himself (Dr. d'Herelle) and as described by himself (Dr. Twort). Dr. Twort thought that these apparent differences could be accounted for by the slight difference in the technique used and in the undoubted difference in the degree of activity of the lysins in different cases. It also appeared to him that whereas the lytic action might not extend when the micro-organism had overgrown the tube of media and used up all the food supply in his specimens, the same lytic action would naturally extend where a very active lysis was present which

prevented the micro-organism from growing sufficiently to use up the whole of the food supply. This explanation was consistent with our knowledge that the lytic substances would only act to any extent when the cultures were actively growing or in a medium suitable for active growth.

In his reply Dr. d'HERELLE said it was impossible for him to answer without preparation the new objections put forward against his conception concerning the nature of the bacteriophage; he must in the first place carry out some cross experiments. As soon as they were finished, he would be able to give a formal reply. He wished, however, to make a preliminary remark: he thought the very interesting work of Dr. Fleming constituted a strong argument in favour of his own conception. If the dissolution of the bacteria in the serial phenomenon was due to an enzyme contained in the bacteria, as many bacteriologists believed, this enzyme must be detected in the filtrate obtained from a culture dissolved by the Fleming process. On the contrary, this last phenomenon was not a serial one. It was a proof that the bacteria did not contain in themselves the principle capable of producing the serial lysis. Concerning the rôle of the bacteriophage in immunity, brought up in discussion by Dr. Ellis, he declared that not only did his own experiments show this rôle, but many other authors had made successful experiments on this line. He cited those of Bruynoghe, Gratia, and others in connexion with staphylococcus infections; those of Bekkerich and Haudnroy on typhoid; those of Bekkerich and Haudnroy, Gorten, Philibert, and others on coli infections. In reference to the problem of the similarity or dissimilarity between the principle discovered by Dr. Twort and the bacteriophage, he repeated that the particularities of the two phenomena, as described by Dr. Twort and himself, were very different. It remained to make a close examination concerning the properties of the two principles, such as resistance to the action of physical and chemical agents, as well as to investigate the process of the destruction of the bacteria, etc., for definitively clearing up the question. In any case, the discovery of Dr. Fleming showed that the bacteriolysis could be produced by various different processes. Finally, he said a word about the claim of Professor Bordet. It seemed to him that he had described his conception of the phenomenon quite in the same way as Bordet himself, as it appeared in his own paper. "It will be obvious, then, that this transmissibility in series eliminates hypotheses 1 and 2. The authors who have put forward these hypotheses must admit that the principle derived from the organism which is attacked by parasites . . . plays only the rôle of a transformer—that is to say, it gives rise, in the bacteria which undergo the transmissible lysis, to a special state of 'antolysability.' Only Bordet and Ciucu have attempted to give an explanation of this. For them the leucocytic principle would provoke in the bacteria an hereditary vitiation of nutritional nature." This, he declared, was just the claim of Professor Bordet.

DISCUSSION ON THE BACTERIOLOGY OF INFLUENZA.

(SIR WILLIAM LEISHMAN, K.C.M.G., C.B., F.R.S., in the Chair.)

OPENING PAPERS.

I.—MERVYN H. GORDON, C.M.G., C.B.E., M.D.,
Bacteriologist and Lecturer on Bacteriology, St. Bartholomew's Hospital.

[With Special Plate.]

THE pandemic of influenza during 1918-19 served to bring home very forcibly the importance of microbiological knowledge, for there is good reason to believe that the severe defeat then suffered by preventive medicine was due in great part to our ignorance with regard to the primary infective agent of this disease. In these circumstances it is clearly the duty of bacteriologists to make all possible use of opportunities that may occur of investigating cases of influenza, and to submit their observations for discussion and criticism at meetings such as the present one. I propose to bring before you some studies made during a recent outbreak, but before doing so will attempt to review the knowledge at present available.

As the differential diagnosis of influenza from purely clinical criteria is necessarily imperfect, it would appear that the best way of approaching the subject from the

bacteriological standpoint is to study not only influenza, but also as many forms as possible of catarrh of the respiratory passages. Because it is characterized at its onset by a condition of profound catarrh, measles also should be included within the purview. Such comparative observations are desirable first in order to gain perspective, and secondly because solution of the etiology of the common forms of catarrh may provide a key to the more virulent disease of this group which we call influenza. Moreover, since over a quarter of the annual mortality in this country is attributable to conditions resulting from infection of the respiratory passages—and perhaps a still larger proportion of the annual illness is due to respiratory infections—the systematic study of the bacteriology of this region is clearly a matter of great importance.

It may here be mentioned that, in view of recent advances in our knowledge, the methods of examining secretion from the upper respiratory passages bacteriologically should include examination of films of the fresh material stained not only by Gram's stain, but also by some specially intensive stain, such as that of Giemsa. For a similar reason cultures on agar enriched with ascites fluid, blood, etc., should be supplemented, when practicable, by diluting a representative specimen of the secretion, or a mixture of such samples, and then, after passing the diluted secretion through a Berkefeld or Chamberland filter, cultivating the filtrate in a medium enriched with fresh tissue, such as the well-known medium of Noguchi.

The Bacteriology of Catarrh.

Studies of individual cases, or of outbreaks of catarrh, have shown that a variety of bacteria occur in the respiratory secretions during this condition, among the most common being *M. catarrhalis*, pneumococci, and the diphtheroid organism first described by Cantley, and later renamed by Beuhm *B. septus*. From time to time also Pfeiffer's bacillus is met with. In the more chronic forms of bronchial catarrh, in addition to the above bacteria, streptococci, Gram-negative bacilli, and even anaerobic organisms of the streptothrix category, may be met with. The precise significance of non-haemolytic streptococci of the *salivarius* or *viridans* class is difficult to assess, because they are so constant and plentiful in normal saliva; but the importance of haemolytic streptococci in some of the more severe and fatal kinds of bronchopneumonia is beyond question. We are much in need of systematic observations on the relative frequency of the more prominent catarrh bacteria in different outbreaks, and especially of the carrier rate of them in communities before, during, and after severe outbreaks.

In addition to the bacteria referred to, evidence is accumulating that in the secretion of the upper respiratory passages during the acute stage of the common cold in the head there occur micro-organisms so minute that they traverse filters which hold up even the very small bacillus of Pfeiffer. It is to these "filter passers" that I wish especially to draw your attention.

General Properties of Filter-passing Micro-organisms.

If anyone makes a list of the infectious diseases and then crosses off those in which the infective agents have been established, he cannot fail to be impressed by the number in which the specific cause has still to be defined. Now the viruses of diseases such as measles, mumps, poliomyelitis, variola, etc., are known to be capable of passing through filters that hold up ordinary bacteria, and this fact indicates that their respective infective agents must be less than 0.5 of a micron in size. Such very minute objects will not be easy to make out even with the highest powers of the microscope, and the term "invisible" or "ultramicroscopic" which has been applied to them would appear to be premature until the possibility of staining them has been explored a good deal

farther than appears to have been the case up to the present time. The majority of the filter-passing organisms that have been seen so far seem to bear a close resemblance to one another in size, shape, and arrangement. Thus the minute organisms observed in variola, vaccinia, poliomyelitis, and molluscum contagiosum vary between 0.1 and 0.3 of a micron in size. They are round or oval in shape, occur as single spherical elements or as diplococcal forms, may be grouped in little clusters, and exceptionally are arranged in a short chain. They fail to stain (or stain very feebly) by the staining methods in common use for demonstrating bacteria, and are negative to Gram's stain. From the excellent article of Lipschitz on these organisms it would appear that in order to demonstrate them it is advisable first thoroughly to fix the film in some powerful fixative such as methyl alcohol, osmic acid vapour, sublimite, etc. Next prolonged staining in Giemsa may be employed, followed by careful differentiation in acetone and xylol. Chief success, however, appears to have been obtained by Continental workers with Loeffler's flagella stain; so that, unless Giemsa is used, in order to render these organisms visible the preparation requires (1) fixation, (2) mordanting, and (3) intensive staining by a powerful dye such as freshly prepared hot carbol-fuchsin. A further point to be noted is that when they have been rendered visible by successful fixing and staining, these minute micro-organisms may be found present in the infective

material in such enormous numbers that it is advisable to dilute this material as much as a thousand times before making films of it in order to examine individuals. So far these filter-passing organisms do not appear to grow to any extent on ordinary culture media; those of them that have been cultivated grow best under anaerobic conditions in a medium containing a piece of tissue such as Noguchi's medium. Their resistance to heat is comparatively low—they may fail to survive heating for half an hour to 55° C. On the other hand, they withstand glycerination for prolonged periods, and thus differ from the majority of the known pathogenic bacteria.

Von Prowazek has called these filter "chlamydozoa," but Lipschitz has "strongyloplasma" (*strongylos*, round) for them. From their minuteness, their striking resistance to ordinary stains, and their strictly parasitic character, these micro-organisms are very difficult to investigate. Nevertheless there is reason to believe that progress is gradually being made with regard to their elucidation.

Observations on the Presence of a Filter-passing Virus in Acute Coryza.

The first person to demonstrate the presence of a filter-passing virus in the common cold was Kruse, who in 1914 succeeded in producing colds experimentally by means of a filtrate of the nasal secretion from a case of acute coryza. The nasal secretion was diluted fifteen times in normal saline, passed through a Berkefeld filter, and a few drops of the filtrate instilled into the nostrils of 12 men, 4 of whom developed acute coryza. The experiment was repeated on a larger scale, and out of 36 students into whose nostrils the filtrate was instilled 15 developed coryza within one to four days. Kruse was unable to demonstrate living organisms in this filtrate by ordinary bacteriological methods, and concluded that the common cold is due to a filterable virus. During the winter of 1915-16 Colonel George Foster of the U.S. Army Medical Corps succeeded in confirming Kruse's observations. In the first place, he was struck by the paucity of ordinary bacteria in the nasal secretion at the onset of coryza—an observation with which others agree who have examined the secretion at that stage by the ordinary staining and culture methods. Nasal secretion from 3 cases in the acute stage of coryza was diluted in saline, passed through a

DESCRIPTION OF SPECIAL PLATE.

FIG. 1.—Filter passer in culture. Preparation from a primary culture in Noguchi medium inoculated with filtered nasal secretion at the onset of influenza. The culture was diluted 500 times before making this film. Note the minute size of the organism, its arrangement, and the diplococcal form. Giemsa's stain. (Magnification 1,000.)

FIG. 2.—Nasal secretion unfiltered. Nasal secretion at the onset of influenza, showing the filter passer and staphylococcus in situ. Giemsa's stain. (Magnification 1,000.)

FIG. 3.—Vaccinia organism. Vaccine lymph mixed with staphylococcus. Note the abundance of the organism described by Paschen, and its small size in comparison with the staphylococcus. Loeffler's flagella stain. (Magnification 1,000.)

FIG. 4.—Nasal secretion containing catarrhal bacteria. Nasal secretion from a case of subacute catarrh, showing *M. catarrhalis*, pneumococci, and Pfeiffer's bacillus in situ. Stain, Gram-fuchsin. (Magnification 1,000.)

FIG. 5.—Pfeiffer's bacillus from a culture on blood agar. Stain, Gram-fuchsin. (Magnification 1,000.)

FIG. 6.—Noguchi cultures from filtered nasal secretion at the onset of influenza. The right-hand tube shows a cloudiness near the kidney and extending for a limited distance up the tube. The left-hand tube was heated to 55° C. for thirty minutes after inoculation, and has remained unchanged. (Natural size.)

Illustrating the paper by C. BENNETT, J. W. S. BLACKLOCK, and C. H. BROWNING.

FIG. 1.—From a burn of the third degree on the forearm of a woman, aged 35 (due to paraffin oil), after seventeen days; treated by daily dressing with proflavine 1 in 1,000. Abundant formation of granulation tissue in fat is shown. ($\times 60$.)

FIG. 2.—From a burn of the third degree in a man, aged 37 (due to burning coal); treated with proflavine 1 in 1,000. Well-vascularized surface there are corpuseles. ($\times 60$.)

FIG. 3.—From a burn of the third degree on the arm of a girl, aged 12 (due to boiling water); specimen taken after application of proflavine 1 in 1,000 for sixty-four days. The section is stained with haemalum and eosin. Well-vascularized granulation tissue is seen, on the surface of which is a thin layer of cellular exudate, which appears to be necrotic. ($\times 250$.)

FIG. 4.—The same as Fig. 3, but stained with eosin and methylene blue. By this procedure the polymorphs constituting the layer on the surface of the granulation tissue appear well stained, in contrast to what is seen in Fig. 3. ($\times 250$.)

FIG. 5.—From the same case as Fig. 2, showing healing of the skin. The layer of extending epithelium, which is in course of covering the granulation tissue, shows the characteristic thin margin. The surface had been dressed continuously with acriflavine 1 in 1,000 for seventy-four days. ($\times 250$.)

FIG. 6.—From a case treated with proflavine for forty days. The progress of healing is somewhat advanced. The surface is covered by a layer of granulation tissue, which is progressing actively. ($\times 60$.)

Berkefeld filter, and the resulting filtrate found to be sterile when sown on ordinary media. Three to six drops of it, nevertheless, when instilled into the nostrils of 10 healthy soldiers, resulted in 7 of them developing acute coryza within eight to thirty hours. The symptoms were quite typical: the majority developed a profuse rhinorrhoea on the second day, 5 developed a cough, 4 suffered from aching pains in the back or extremities, and in 6 the temperature ranged between 99.2° and 100° F. The duration of the symptoms was from three to six days. The experiment was carefully controlled, and there was no epidemic of colds at the time in the garrison where the experiments were made.

Having found that ordinary bacteriological methods failed to reveal any organisms in the filtrate, Foster proceeded to cultivate it in the tissue-ascites medium of Noguchi. It is to be noted that he devoted eighteen months to mastering the technique of this method, and that he warns investigators that for success the greatest patience and care are needed—a warning I can heartily endorse. In the outcome Foster succeeded in cultivating from the filtrate of the nasal secretion during the acute stage of coryza a minute organism which he describes as consisting of coccoid bodies 0.2 to 0.3 micron in diameter, arranged singly, in pairs and groups, and bearing a resemblance to the so-called globoid bodies found by Flexner and Noguchi in similar cultures from poliomyelitis material.

Apparatus for filtering. 1. Flask with saline geyser; 2. paper filter; 3. Berkefeld filter of shape shown in 5, held in position by rubber cap; 4 and 6. The receiver of the Berkefeld filter is connected to a manometer and air pump. A minus pressure of 10 cm. of mercury is applied.

A dilution of these positive cultures was passed by Foster through a Berkefeld filter and the filtrate instilled into the nostrils of 11 volunteers, 10 of whom, after an incubation period corresponding with that of the first series, developed symptoms of coryza that persisted for several days. The nasal secretion of this second series was filtered in turn, and the organisms recovered from the filtrate by culture in Noguchi medium. Foster concluded that the common cold is infectious; that its virus is present in the nasal secretion; that it is a "filter passer," and is represented in all probability by the minute micro-organism which he succeeded in cultivating. The lack of success of the later attempt by Branham and Hall to cultivate filtrable viruses from cases of colds and influenza may have been due to the fact that most of their material was taken after the second day of the disease; and, to judge from my own experience, it is probable that the ascites fluid used by them, though suitable for hardier organisms, was too alkaline for these exceedingly fastidious micro-organisms.

THE BACTERIOLOGY OF INFLUENZA.

While the toxicity of Pfeiffer's bacillus is generally admitted, and also the important part which it plays in the majority of the severe cases of influenza, there are several points that militate against its candidature for the place of primary infective agent. The first is the significant fact that numerous experiments have been made, especially in America, by infecting human volunteers with Pfeiffer's bacillus without producing influenza. It is true that Blake and Cecil have shown that if the virulence of Pfeiffer's bacillus is raised by animal passage this micro-organism when introduced into the nose of a monkey can produce local and general symptoms and lesions broadly resembling those of influenza; but when Cecil and Steffen repeated this experiment by injecting the nares and pharynx of human volunteers with such a virulent culture, they found that while a condi-

tion resembling coryza was produced the symptoms were not quite those of influenza. A further point that tells greatly against Pfeiffer's bacillus is its absence in a proportion of cases of undoubted influenza, and another is the circumstance that bacilli having the morphological and cultural characters of this bacillus may be found in swarms in the bronchial secretion of a considerable proportion of the children who succumb during an attack of measles, the primary agent of which disease is known to be a filter passer.

On the other hand, there is definite experimental evidence that in influenza, as in the common cold, the primary infective agent is a filter passer. During the late epidemic several positive experiments were reported on human volunteers with the filtrate of material derived from cases of influenza, but perhaps the most striking were those of Yamanouchi and his colleagues. These Japanese observers made excellent use of 52 of their colleagues—doctors and nurses—who volunteered for experiment. Sputum from 43 cases of influenza was emulsified and injected into the nose and throat of 12 healthy persons, and the Berkefeld filtrate of the same material was injected in the same way into 12 more. The results were highly significant: 6 of the subjects had recently had influenza and these escaped; all of the remaining 18, after an incubation period of two to three days, developed influenza. A filtrate of blood from influenza patients was injected into the nose and throat of 6 more healthy persons, again with positive result. They next tried the subcutaneous route, using the filtrate of sputum or of blood of patients; all the subjects developed influenza except one, who had previously had the disease. Lastly, a pure culture of Pfeiffer's bacillus and a mixed preparation of the organism of Pfeiffer with pneumococci, streptococci, and other bacteria common in influenza sputa, were injected into the nose and throat of 14 healthy persons, with the result that no symptoms or illness followed. The Japanese observers point out that in their experiments all persons who had had influenza or who had received the sputa emulsion or its filtrate became immune. These experiments are of great importance. Had an observation been made with the filtrate after heating it for half an hour to 55°C. they would have been still more complete.

Since it is the secondary lesions that kill in influenza, it was to be expected *a priori* that animal experiments to define the primary infective agent would be far less convincing. Thus Andrewes has pointed out that the lesions described by Gibson, Bowman, and Connor in animals that succumbed to inoculation with the filtered material from cases of influenza or from cultures in Noguchi medium are generally similar to those obtained by others with the filtrate of Pfeiffer's bacillus. The filtrate of Pfeiffer's bacillus, however, has been tried on human volunteers by Cecil and Steffen without effect.

The successful efforts of Gibson and others during the pandemic of 1918-19 to obtain cultures of a filter passer from cases of influenza indicated that during the first three days of the disease, but not later, a minute micro-organism similar to that found by Foster in colds is present also in influenza. These observations, however, were not conclusive. Since that time Olitsky and Gates have published a series of observations which have not only confirmed and added precision to those of previous investigators, but also promise to place the matter of the primary infective agent in influenza on a new and firm experimental basis. Starting with the nasopharyngeal washings of cases before the third day of the disease, they showed that this material *unfiltered* produced on intratracheal injection into rabbits a leucopenia falling especially on the lymphocytes, fever, and pulmonary lesions characterized by haemorrhage, emphysema, and oedema. The important point was that Olitsky and Gates were able to transmit this "syndrome" in series, and to carry it on from rabbit to rabbit even for as many as fifteen passages. Controls made in the same way with nasopharyngeal washings from 16 non-influenza cases, including cases of coryza, also from cases of influenza after the second day, proved negative. Foreign protein (for example, human ascites fluid), *B. influenzae*, or its toxin prepared by Parker's method, all gave negative results. Having thus found that the nasopharyngeal secretion of patients at the onset of influenza has a peculiar pathogenic effect on the rabbit, they proceeded to show that this action is retained by the secretion when the bacteria have been removed from it by a Berkefeld filter. Still using this peculiar rabbit reaction as guide, they next showed that the pathogenic agent present in nasopharyngeal secretion resists 50 per cent. of glycerin for periods up to nine months, and finally that it consists of a minute "bacilloid" body

0.15 to 0.3 micron in length, which they cultivated in Noguchi medium, using ascites fluid having a pH of not over 8, and preferably 7.8.

In papers published during the present year Olitsky and Gates report that they have succeeded in growing the filter passer anaerobically in fluid media containing reducing agents such as ordinary bacteria or vegetable tissue, and also on ordinary agar without further enrichment than 5 per cent. of rabbits' blood. On the latter medium fine colonies are formed within a week and the organism may grow into a spindle-shaped rod as much as a micron in size. Furthermore, by cross-tests they have succeeded in obtaining evidence of the identity of the immunity resulting in the rabbit from injection with the nasopharyngeal secretion of influenza patients, the Berkfeld filtrate of this material, or the filter-passing micro-organism isolated from either of these materials. This immunity appears to endure in the rabbit for at any rate fourteen months. Lastly, they have succeeded in establishing experimentally the formation of specific antibodies such as agglutinin, complement fixing antibodies, and bacteriotropins to this anaerobic filter-passing micro-organism.

PERSONAL OBSERVATIONS.

Early in the present year a sharp outbreak of influenzal illness occurred among the nursing staff of St. Bartholomew's Hospital. I am indebted to Dr. W. P. S. Brausen for the following particulars of the epidemic: Between December 23rd, 1921, and January 23rd, 1922, 57 nurses were attacked, the majority between December 25th and January 3rd. The disease was characterized by its sudden onset and by the fact that for the time being it completely incapacitated those affected. The average duration was three days' febrile illness, necessitating a stay of altogether five days in bed and an average absence from duty of seventeen days. Signs and symptoms at the onset were congested conjunctiva and facies, coryza, furrowed tongue, rapid pulse, and pain in the back. The average highest temperature was 102° F. With regard to complications, those fortunately were rare; one case developed bronchitis that did not pass into pneumonia, and one case of mastoiditis occurred.

The diluted nasal or pharyngeal secretion of 4 nurses within thirty-six hours of the onset of illness was put through the Berkfeld filter, and 1 c.c.m. amounts of the respective filtrates cultivated in ordinary media and in Noguchi tubes. While the former cultures remained sterile, the latter showed in each case on the fourth to sixth day a "cloudiness" near the piece of kidney, precisely in the manner described by Olitsky and Gates. In each case a control Noguchi tube inoculated with the same amount of filtrate and then heated for thirty minutes to 55° C. remained free of cloud over this period, as also did a control tube of the medium left uninoculated. On examining the positive cultures with Gram's stain no bacteria could be found, and subcultures on ordinary media failed to grow.

When films of material taken from the foot of the positive cultures were fixed in methyl alcohol for twenty-four hours, and then stained in 5 per cent. Giemsa for a similar period and lightly differentiated in equal amounts of acetone and xylol, swarms of minute round bodies, which had for the most part a purple or reddish tint, were revealed (Fig. 1). Having failed to find these bodies in the control tubes, I proceeded to look up the literature of filter-passing micro-organisms, and was much struck by the photographs of those found by Paschen in vaccine lymph, which are included in the review of filter passers by Lipschutz in Kolle and Wassermann's textbook. Having obtained some fresh vaccine lymph through the courtesy of Mr. Fromlin, I proceeded to examine films of it after the manner recommended by Paschen, and after some difficulty succeeded in finding these bodies by using a modification of Loeffler's flagella stain (Fig. 3).

Having come to the conclusion that these bodies in vaccine lymph are of the same order (as regards size, shape, and general appearance) as those present in the influenza cultures, I have since that time been endeavouring to acquire the necessary skill to enable me to investigate these most minute micro-organisms, and I am very conscious of the magnitude of the technical difficulties and of the comparatively slow progress that has been made. Results up to the present time are briefly as follows:

Primary Cultures.—Through the kindness of colleagues, and of the medical departments of the Ministry of Health and the London County Council, I succeeded in obtaining material during the late outbreak of influenza in London from 16 further cases within

thirty-six hours of the onset of symptoms, and cultivated the filtrate from each in Noguchi medium as before. Out of the total of 20 cases (including the nurses) in which the filtrate of the nasal or pharyngeal secretion was examined in this way I obtained evidence of the presence of a filter-passing organism in 14. In addition, filtrates from the bronchial secretion were cultivated from three fatal cases of influenza, with positive results in two. The secretion that gave the best growth of the filter passer was literally ex-; this bacillus, however, failed to; addition to the above cultures I; from 7 cases of measles at the onset of the rash. In 3 of these cases the filtrate produced some clouding of the Noguchi tube on the fourth to seventh day, and in two of these cultures I succeeded in satisfying myself of the presence of a filter-; similar in morphology to that found in the; with these positive cases, however, probably; from the same strain of virus; and there are clinical grounds for thinking that they were in reality cases of German measles.

Subcultures.—After three weeks' growth three of the primary influenza cultures were diluted, filtered, and the filtrate sown in fresh Noguchi tubes. Two gave a positive growth; in the third the result was doubtful.

Demonstration of the Filter-passing Organism in situ in the Secretion.—As neither Foster nor Olitsky and Gates mention any observations on this point, I have investigated the matter; and in both of the last two cases of influenza have succeeded in demonstrating the minute filter-passing organism in large numbers in the nasal secretion during the first twenty-four hours of the disease (Fig. 2). In both cases the secretion was clear and ordinary bacteria were scarce. The stain used successfully was Giemsa, the stained preparations being differentiated as before in xylol and acetone. Confirmatory results were obtained in both cases with methyl-blue and in the last one with Azar I as well. Both secretions were filtered and found to yield a positive growth of the filter passer on the third to fourth day. The first case developed symptoms of gastric catarrh two days later, but was well again in a few days, and when his nasal secretion was re-examined, eleven days from the onset, no certain filter passers were found either by film or by culture of the nasal secretion.

The morphology of the filter-passing micro-organism from the influenza cases has been referred to previously. I cannot help thinking that the name proposed for this organism by Olitsky and Gates, *Bacterium pneumosintes*, is somewhat premature. The feeling I have is that we are dealing with a new field, so to speak, and that the individual members had better not be given elaborate names until we have agreed upon some common name for the whole group, to which a distinctive name for each member may be added later.

It is, I think, self-evident that the relatively slow progress that has been made with the elucidation of filter passers is due to the fact that these micro-organisms require a technique far more difficult to acquire than that in use for dealing with ordinary bacteria. We are badly in need at present of some simple and fairly quick staining method that will tell us for certain whether these minute organisms are present or not in a given material. For this purpose Loeffler's flagella stain is too complicated, uncertain, and dirty. Giemsa's is far cleaner and less liable to error, but the long time required for fixing and staining is a drawback, and the final differentiation needs the greatest caution or the finest preparation may be ruined. Furthermore, Giemsa's stain may fail occasionally to reveal filter passers, even when these are present in large numbers. Olitsky and Gates use methylene-blue (either polychrome or Loeffler's), but the specimens of methylene-blue I have been able to obtain are, and all refuse to stain filter passers. My best results so far have been obtained with a sample of methyl-blue obtained in 1912 from Grubler. It is of course essential to fix these organisms very thoroughly before attempting to stain them. A mixture of equal parts of absolute alcohol, acetone, chloroform, and ether makes a good fixative and seems to clear the ground—a great source of error in this work. After air-dried coverslip preparations have been immersed in this mixture for half an hour I place them in absolute alcohol for the same time, then dry them and place them in 1 to 5 per cent. acetic acid for a few minutes, after which they are left in 1 in 200 to 1 in 400 methyl-blue overnight, either at room temperature or at 37° C. When other methods fail I fix two preparations in the manner stated, then warm one in 1 per cent. acetic acid, the other in 1 per cent. NaOH, and after washing in water and alcohol stain both with hot, well-filtered carbol-fuchsin for five to thirty minutes at 55° C. It would seem that the very reluctance of filter-passers to stain with the ordinary bacterial stains can be applied to differentiate them from bacteria. Thus a mixture containing 1 in 5,000 to 1 in 10,000 of ordinary basic fuchsin and 1 in 200 to 1 in 400 of methyl-blue has been found to stain staphylococci a brownish-red colour, and the accompanying filter passer a light blue. It is not every

specimen of methyl-blue, however, that is successful; so that the value of this and other stains for the purpose is a matter urgently calling for investigation.

Search for the primary infective agent in influenza, therefore, has led us into the realm of filter-passing micro-organisms, and is fast tending to place this disease in the same category as measles, variola, poliomyelitis, foot and mouth disease, and many others of this difficult and mysterious group. It would seem that the chief importance of Pfeiffer's bacillus and other catarrh bacteria is in relation to the severity of the disease.

It should be noted that these minute filter-passing organisms are distinguished from albumin precipitates by the uniformity of their size, by the sharpness of their contour, and also by their resistance to caustic potash, acetic acid, ether, chloroform, and trypsin. Further points to bear in mind are the constancy of these organisms in the particular pathological secretions in which they occur, their vast abundance in such materials (corresponding with the high infectivity), and their absence in control materials. Lastly, the evidence that has recently been brought forward by Olitsky and Gates to show that the filter passer of influenza excites the production of specific antibodies is a promising step forward, and is paralleled by the similar claim of Beliu and of Paschen in respect of the filter-passing organism of vaccine lymph.

II.—JAMES McINTOSH, M.D. ABERD.,

Professor of Pathology, University of London; Director, Bland-Sutton Institute of Pathology, Middlesex Hospital.

The etiology of epidemic influenza has been in recent years the subject of much discussion and research, but many difficulties lie in the way of the complete elucidation of the problem. Perhaps the greatest difficulty arises from the fact that influenza is mainly a clinical concept and in all likelihood includes a number of respiratory infections.

Since Pfeiffer, nearly thirty years ago, claimed his *Bacillus influenzae* to be the cause of the disease much research has centred round this bacillus, and two parties have grown up, one of which favours this organism as the etiological agent, while the other considers that the cause is still to be discovered. Many of the latter believe that the virus is ultra-microscopic. The hope that the next great epidemic would decide definitely the part played by *B. influenzae* has not been fulfilled.

I propose here to give a short account of some personal observations on the bacteriology of epidemic influenza made during the late epidemic and forming the basis of a special report to the Medical Research Council.

The first wave of the late epidemic appeared in the early summer of 1918 at a most critical period of the great war, and found the majority of bacteriologists unprepared to tackle the problem. Much useful preliminary information was, however, obtained and greatly facilitated work at a later period. This is particularly true in regard to methods of isolation and cultivation of the bacillus of Pfeiffer. Naturally the majority of bacteriologists first turned their attention to this bacillus, and although the findings were at first conflicting, later they were more uniformly positive. The researches may for the sake of convenience be subdivided into cultural, histological, serological (relating to filter-passing virus), and experimental observations.

1. CULTURAL OBSERVATIONS.

The majority of the observations were made in the epidemic period from July, 1918, to April, 1919, when material from all types of influenza was examined.

Technique.

Film preparations were made and stained by Gram's method and counterstained by neutral red or weak fuchsin, and a rough estimate made of the various types of bacteria present. By this means valuable information was obtained as to the type of bacteria predominating.

For the actual isolation of the bacteria three different media—ordinary agar, serum agar, and Matthew's trypticized blood media—were used. Matthew's medium has great selective power towards the growth of *B. influenzae*, at the same time inhibiting to a large extent cocci and other bacteria. In each case these three media were used, and after plating out and incubating an estimation of the different colonies was made.

Incidence of Various Bacteria.

As considerable numbers of bacteria are always to be found in any catarrhal condition of the respiratory passages a mere statement of their presence or absence is of little or no value. But by the use of the technique described above a good indication of the type of micro-organism predominating can be arrived at, as the following figures show:

(a) *Acute Uncomplicated Cases* (from a local epidemic among the nurses of the London Hospital).—As these cases had practically no bronchial secretion examination by nasopharyngeal swabs was carried out. The number of cases examined was 17; positive 13 = 76.4 per cent.

(b) *Acute Influenzal Bronchopneumonia* (sputum examination).—Seventy cases were examined and the following organisms found:

<i>B. influenzae</i>	82.8 per cent.
Pneumococci	31.4 "
Streptococci	34.2 "
Staphylococci	27.1 "
Gram-negative cocci	32.8 "

(c) *Post-mortem Material* (bronchial secretion and lung juice).—Sixty-eight cases were examined, of which 48 had lesions which were macroscopically characteristic of acute influenza.

<i>B. influenzae</i>	75.0 per cent.
Pneumococci	28.8 "
Streptococci	36.6 "
Staphylococci	22.2 "
Gram-negative cocci	28.8 "

A complete differentiation of the pneumococci and streptococci was not possible in this research, but fermentations were always carried out. Blood cultures were sterile unless the cases were in *extremis*, when occasionally streptococci were found. Pus from complicating empyemata contained streptococci or pneumococci, and on two occasions *B. influenzae*.

Observations on a series of cases of gastric influenza indicated that the condition was mainly toxæmic, and only once were definite lesions of an embolic nature found in the intestine *post mortem*.

Incidence of *B. influenzae*.

B. influenzae, therefore, proved to be the most frequent pathogenic microbe present in the various pathological secretions of acute influenza during the height of the epidemic. In the smaller wave of January, 1922, similar findings as regards the frequency of *B. influenzae* were obtained both in uncomplicated and fatal bronchopneumonic cases.

2. RELATION OF THE VARIOUS MICRO-ORGANISMS TO THE PATHOLOGICAL LESIONS.

Histological examinations of *post-mortem* material showed that epidemic influenza is primarily an acute catarrhal inflammation of the respiratory tract with a maximum involvement of the lungs. Briefly, the characteristic lesion in the latter is a diffuse bronchopneumonia with a haemorrhagic oedema.

At a very early stage bacteria are to be found in considerable numbers in the upper respiratory tract, but are rare in the lungs. Later the lungs contain large numbers. In the mucosa of the trachea and bronchi bacteria were usually found in large numbers in the mucous exudate, on the surface of the mucosa, and deep amongst the epithelial cells. In many cases numerous small Gram-negative bacilli (*B. influenzae*) were found among the unshed epithelial cells. At times cocci of various types, alone or associated with *B. influenzae* types, were found in the exudates and lymph channels of the sub-mucous tissues. The types of bacteria found corresponded closely with the cultural examinations.

3. QUESTION OF A FILTER-PASSING VIRUS.

A search was also made for the presence of a filter-passing virus in acute influenza cases. The filtrates (Berkfeld) of nasal washings, throat washings, and lung juice were inoculated into tubes of Noguchi medium and into a number of

laboratory animals and monkeys. Three of those experiments may be quoted.

1. The filtered nasal washings from two early uncomplicated cases of influenza were inoculated into two *Macacus rhesus* monkeys, four rabbits, and two guinea-pigs.
2. The filtered throat washings from three early cases were inoculated in the same way, but 8 c.c. was given subcutaneously to a *Macacus rhesus* and a Husar monkey.
3. The filtered lung juice from three acute fatal cases was inoculated in the same way into a dog-faced monkey (*Macacus rhesus*) and two rabbits.

With one exception all the inoculations were without effect. The exception was the dog-faced monkey; this animal ten days later developed a running at the nose and a temperature of 103.2° F., but an uninoculated monkey in the next cage also had a bad cold. The animal gradually got weaker and died thirty-four days after the inoculation. A necropsy showed accumulations of fluid in the pleural and pericardial sacs. The lungs showed only a few consolidated areas. The spleen was slightly enlarged and showed a number of small yellow areas. Bacteriological and histological examinations showed a recent septicaemia with milky abscesses. Passage inoculations were without result. I do not consider that in the above instance we were dealing with an infection of an influenzal nature. Similarly, the inoculated Noguchi tubes gave uniformly negative results when injected into animals.

During the recrudescence of January, 1922, I took the opportunity of repeating the search for a filter-passing virus. In this series a number of clinically acute influenza cases of only a few hours' duration were obtained from a large Government department, the average length of illness being only a few hours. The nasopharyngeal secretions were diluted to an adequate extent and filtered through a Berkefeld filter and then inoculated into Noguchi tubes and laboratory animals. A few of the Noguchi tubes developed a diffuso cloudiness; some of these proved sterile, but in others a slow-growing coccus or a small diphtheroid bacillus was found. The majority of the tubes remained sterile to ordinary tests, and with these animal inoculations were negative.

Table of Observations made in January, 1922.

- No. 1. H.N.N., aged 15; ill for two hours. Pulse 100, temperature 99.5°.
- No. 2. F.D.; ill one hour; rigors, coryza. Temperature 100°, pulse 108.
- No. 3. J. J. B., aged 40; ill for twelve hours; rigors, pains in back, etc. Pulse 114, temperature 99°.
- No. 4. F.W.; ill one hour. Temperature 100°, pulse 120.

Result of Noguchi Cultures.

1. All tubes remained clear as control; observed fourteen days.
 2. Faint turbidity in one tube after forty-eight hours; later found large staphylococcus.
 3. All tubes sterile.
 4. All tubes showed very faint turbidity in twenty-four hours, which gradually spread up the tube. Subcultures yielded no further opacity and were sterile.
- B. influenzae* was seen and isolated in Nos. 2 and 4, while very suspicious forms were found in No. 3.

Serological Observations.

Agglutination and complement fixation tests were carried out on the serums of convalescent influenza patients and gave positive readings, chiefly again *B. influenzae* in many cases. In the case of the complement fixation test 12 out of 19, or 63.3 per cent., were positive. Only once definite lesions were found *post mortem*.

Attempts at Experimental Transmission of Epidemic Influenza.

In the section dealing with the search for a filter-passing virus it is noted that animal inoculation with filtered pathological secretion from cases of influenza failed to produce disease in the animals. In order to show that the virus was not held up by the filter a series of similar experiments was made using unfiltered nasal and nasopharyngeal secretions. The injections were made subcutaneously, but without result. Negative results were also obtained on monkeys even when the secretions were instilled directly into the nose. In one case the inoculated nasal secretion was shown to be heavily infected with *B. influenzae*. Similarly the instillation of cotton-wool soaked in pure cultures of *B. influenzae* failed to produce more than a mere transitory secretion of mucus.

Attempts at Producing an Experimental Influenza.

Experiments were carried out to test the pathogenic effects of cultures and filtrates of *B. influenzae* and the production of experimental influenzal lesions.

The failure of all attempts to demonstrate a virus—filter-passing included—which could reproduce an experimental influenza in animals led me to direct my attention again to the part played by *B. influenzae*, which was almost constantly present in the production of the lesions.

It has been known for some time that a number of influenza strains are highly pathogenic for animals, although they fail to produce characteristic influenza lesions in the lungs; the animals, however, *post mortem* show lesions strongly suggestive of the action of a toxin. Again certain of the symptoms in influenza patients are suggestive of the action of a toxin—collapse, diarrhoea, etc. It was therefore thought advisable to test the effects of filtered and unfiltered cultures for the presence of a soluble toxin. At first not much success was obtained, but later, by using twenty-four hour old cultures in boiled blood broth according to the Parker method, lethal effects could be produced in rabbits and guinea-pigs on intravenous inoculation. In some cases death occurred in a few minutes after the injection; in others partial recovery occurred and the animal died in twenty-four to forty-eight hours, as the following table shows:

	Filtered Culture, Intravenous.	Result.
<i>Experiment I.</i>		
Guinea-pig No. 1 ...	2 c.cm.	Died in a few minutes.
Guinea-pig No. 2 ...	2 c.cm.	
Guinea-pig No. 3 ...	1 c.cm.	
Guinea-pig No. 4 ...	0.5 c.cm.	Survived.
<i>Experiment II.</i>		
Guinea-pig No. 1 ...	1.5 c.cm.	Died almost immediately.
Guinea-pig No. 2 ...	1.0 c.cm.	Very ill, found dead next morning.
Guinea-pig No. 3 ...	0.5 c.cm.	Ill, but survived.

A similar result was obtained in rabbits if the dose was increased to 5 to 7 c.cm.

It has been suggested that the toxic effects of these filtrates might be due to an endotoxin or some protein degradation substance instead of a true toxin, although they have many points in common with true toxins and are thermostable. The crucial test, however, is the production of an antitoxin. By the repeated injection of rabbits a serum was produced which had definite neutralizing properties against the toxin. Normal rabbit serum has only a slight protective power. Unfortunately the complete toxin-antitoxin test broke down, as owing to the relatively large dose of toxin required it was impossible to apply the multiple doses test. With more elaborate technique it is hoped that this may be done at some future date.

Whatever the exact nature of the toxic substances in the filtrates of *B. influenzae* the injection produces histological changes in the animals which bear a striking resemblance to the natural disease. A summary of these is given.

The most suggestive syndrome was observed in guinea-pigs which died four to five hours after the injection. As a rule the animals immediately after the injection became collapsed, the hair stood on end, and they crunched in a corner of the cage. An hour or two later the temperature was found to be subnormal, there was a frothy discharge from the nose, and slight diarrhoea. In the affected animals the pathological changes were often quite striking, particularly in those which died twenty-four to thirty-six hours after the injection. Similar, but less extensive, changes were found in the rabbits. The lungs, as a rule, were voluminous and did not retract fully when the chest was opened. On the surface were to be seen slightly sunken dark red areas of collapse alternating with the pale emphysematous areas. In many definite haemorrhages were seen which at times involved a whole lobe of the lung. On cutting into the lungs, blood-stained frothy mucus escaped in considerable amount.

Microscopically the affected areas showed a typical picture of bronchopneumonia. The bronchioles were plugged with desquamated proliferated few leucocytes. There were haemorrhages in the bronchial walls and the peribronchovascular spaces were infiltrated and contained small haemorrhages. Others contained with desquamated epithelium haemorrhages and conglutination. The suprarenals were shown multiple haemorrhages. The kidneys showed varying degrees of parenchymatous degeneration, with actual necrosis of the epithelium in places. The intestines were usually congested, distended with gas, and showing subperitoneal haemorrhages.

In another communication I have dealt fully with the pros and cons of various claims put forward as to what is the true etiological agent of influenza. *B. influenzae* was found in from 60 to 90 per cent. of cases of influenza in the late epidemic, a figure in close agreement with my own results.

The production of experimental influenza lesions in rabbits and guinea-pigs with the toxin of *B. influenzae* (by the Parker method), and the successful results of Cecil and Blake, who produced an experimental influenza in monkeys with virulent strains of *B. influenzae*, go a long way to establish *B. influenzae* as the primary etiological agent. Indirect evidence is the production in susceptible individuals of a typical influenzal attack of short duration by an injection of a vaccine of *B. influenzae*.

Amongst the arguments which have been put forward against the etiological importance of *B. influenzae* may be mentioned the failure to find the bacilli in a certain number of early cases, and the presence of the bacilli in other diseases and in the throats of a number of normal individuals. Time and further research alone can determine whether a filter-passing virus plays an important part in the etiology of the disease. The claims to a successful demonstration of these viruses have been more than counterbalanced by the negative experiments of others. Most of the successful workers claim to have obtained positive cultures in Noguchi medium, in which a cloudiness develops. It is recognized by those who have considerable experience with this medium that these growing opacities are frequently to be observed in uninoculated tubes, while particles demonstrated by prolonged Giemsa staining are to be found in most albuminous fluids. Again, the majority of the best-known filter-passing viruses have not yet been cultivated with certainty and their presence is only recognized by their lethal effects on animals (typhus fever, small-pox, etc.). Considering, therefore, that a number of these filter-passing viruses (Levadii) are not infrequently to be found in the buccal secretion, any claims as to etiological importance are premature until it has been demonstrated satisfactorily that the virus on injection can produce proliferative changes in the lung such as are found in fatal cases of influenza.

CONCLUSIONS.

1. The predominating micro-organism in the secretions and lesions of the late epidemic was *B. influenzae* (Pfeiffer), which could be demonstrated in from 75 to 80 per cent. of the cases.
2. Other members of the catarrh-producing group of bacteria (pneumococci, streptococci, *M. catarrhalis*, etc.) were much less frequent.
3. Serological examinations confirmed an infection by *B. influenzae*.
4. The possibility of producing, experimentally, influenza-like lesions in the respiratory tract and lungs with filtered cultures of *B. influenzae* was demonstrated.
5. No evidence was obtained in support of the view that influenza is due to a filter-passing virus.

DISCUSSION.

Dr. J. HENRY DIBLE (Manchester) said that one of the initial difficulties in any work upon influenza was the lack of any definite criterion of this disease. Two distinct conditions, or rather two widely differing extremes in a graduated series of cases, were met with. First, there was the disease as it appeared in the early days of the 1918-19 epidemic—a short pyrexial condition accompanied by sore throat and prostration, but devoid of pulmonary lesions. Secondly, there was the condition so familiar in the later phases of the epidemic when pulmonary lesions were so extremely prevalent. The idea now accepted was that these pulmonary lesions were complications due to other organisms, notably pneumococci and streptococci, acting on lungs damaged by the true virus of influenza. It was preferable to study the uncomplicated form, of which lung lesions were no essential part. The only criterion for the disease under these conditions was the leucopenia, associated especially with a fall in the mononuclear cells, upon which Olitsky and Gates have laid stress

in their experimental results. This they claimed to have produced by injection of their filter-passing virus, and considered its production evidence of the relationship of their virus to the clinical disease. Dr. Dible said that he had recently been examining the cellular response to Pfeiffer's bacillus. In all work with this organism it was necessary that the bacillus in question be a certain member of the Pfeiffer group. In examining the throats of normal subjects to ascertain the incidence of Pfeiffer's bacillus a group of organisms had been isolated which belonged to the haemophilic family but not, he considered, to be classed as Pfeiffer's bacillus. The latter was a minute organism, having a restricted ability to split sugars confined to certain monosaccharides. The other group contained large forms and also small organisms closely resembling the influenza bacillus, but they generally showed a much more active power of splitting sugars and a large proportion of them were, in addition, haemolytic. It was possible that some results obtained with organisms believed to belong to the Pfeiffer group might lead to error if the exact properties of the organism in use were not carefully defined. It is found that the intravenous injection of Pfeiffer's bacillus caused a leucocytosis. This infection, however, did not reproduce the conditions of the natural disease, in which the organisms did not invade the blood stream. The injection of small sublethal amounts of the toxins of the organism occasioned, on the other hand, a sharp fall in the leucocyte count, corresponding to the period of collapse and due to a very marked depression of the mononuclear cells. This result was constant and was the condition claimed by Olitsky and Gates to be found with their filter-passing virus and clinical evidence of a condition identical with influenza. Considering the evidence for Pfeiffer's bacillus as a whole, and especially in view of the results obtained by McIntosh with its toxins, and the very striking results obtained by Cecil and Blake, who, with a pure culture of *B. influenzae*, were able to produce a catarrhal condition of the upper respiratory passages spreading spontaneously down the air passages and occasioning bronchopneumonic lesions of the lung in monkeys, Dr. Dible was brought to the conclusion that *B. influenzae* (Pfeiffer) could initiate a disease in all ways comparable to human influenza. On the other side of the subject there was a steadily increasing mass of evidence in favour of the filter passer. There were certain rather obvious criticisms which it was perhaps rather unkind to make in view of the great technical difficulties which surrounded this work, but which must nevertheless be realized. In the first place filtration was a crude procedure. A filter consisted of a mass of fibres, and it was extremely unlikely that manufacturers could produce them constantly of any degree of uniformity. What would pass through depended upon the relationship of the largest hole in the filter to the smallest piece of viable bacterial tissue present in the culture. The whole matter was very difficult, and it was necessary to standardize technique as far as is possible. It should be a reproach to any scientifically trained worker to talk loosely of Berkefeld filtration without reference to the pressure under which it had been carried out and the time occupied in the process. Three out of four Berkefeld filters he had used passed Pfeiffer's bacillus. Apart from these considerations there were other difficulties. Olitsky and Gates stated that their virus was non-pathogenic for monkeys, whilst Gibson, Bowman, and Connor, who were presumably working with a similar virus, obtained many of their results with these animals. The extraordinarily large amounts of material used to produce the results in Olitsky and Gates's experiments were striking. They used, on an average, a dose of 3 c.cm. of fluid injected intratracheally into rabbits to produce comparatively trivial results. This would correspond to about 120 c.cm. of fluid introduced into the trachea of a 12 st. man, a volume of material which might well produce haemorrhagic lesions. Even with their cultures, in which the virus would be extremely concentrated, they had adhered to this enormous dosage. The results obtained by Cecil and Blake with relatively much smaller doses of Pfeiffer's bacillus were much more impressive. These aspects of the matter should be considered. The problem was still unsolved, and was one of extreme difficulty.

Sir WILLIAM B. LEISHMAN, K.C.M.G., C.B., F.R.S., stated that evidence as to the etiological agent in influenza might be derived indirectly from a study of the results of prophylactic treatment with *B. influenzae* vaccines. The results of the preventive measures carried out by the R.A.M.C. in different parts of the world showed that in some cases no

benefit was derived from a mixed influenza vaccine, whereas in other instances marked protection seemed to have been derived from the vaccination.

Dr. LEDINGHAM said that on the balance of the evidence he had no hesitation in subscribing to the view that the essential cause of influenza is something in the nature of a filtrable virus. Pure uncomplicated influenza, as he had seen it in Mesopotamia in the early epidemic wave of 1918, was a mild infection of two or three days' duration. The presence of Pfeiffer's bacillus in these mild cases was admittedly rare, and this fact could not be ignored simply on the ground that the cultural methods then practised were not satisfactory. Aside from culture the organism was not to be seen in stained smears. On the other hand, no one would deny the importance of Pfeiffer's bacillus as the chief contributory cause of the grave pulmonary complications in the later waves of the epidemic. The bodies described by Dr. Gordon and others in cultures from filtrates were of great interest, but the time was not ripe for judgement upon them. It was necessary to wait until the form and staining properties of protein and other aggregates and precipitates were more thoroughly studied and allowed for in all work of this kind. Even the position of the "globoid" bodies in acute poliomyelitis was still *sub judice*.

Dr. F. W. TWORT said that he had been working on influenza for several years. The evidence for and against the presence of an ultramicroscopic virus had been very ably presented, and he did not desire to say much on that subject. He, however, thought it most important in all filter experiments to determine the exact conditions under which filtration was carried out, as many factors influenced the results. In his own experiments on soil filtrates he had on many occasions grown some very delicate and minute organisms which would pass a Berkefeld filter with comparative ease when they were in a fluid emulsion or had been grown in a fluid medium for a short time; yet they showed no evidence of passage when an emulsion was made from a growth of solid medium and filtered immediately. Another point of interest was that these minute organisms would grow in symbiosis with *B. influenzae* on media containing no blood; this showed that blood was not essential for the cultivation of the influenza bacilli, and, moreover, indicated that the influenza bacilli might survive in such situations as soil, a point that might be of importance in connexion with the start of an outbreak. One other point which might be worthy of note: while he would not suggest that the minute micro-organisms obtained from soil were the ultramicroscopic virus, yet, as such a virus is believed by some workers to be the primary causative agent in influenza, it was, he thought, of interest to find that the influenza bacillus would grow so well and easily when cultivated in symbiosis with these minute soil micro-organisms.

Dr. FLEMING (London) remarked on the diversity of agents which might be responsible for initiating a common cold. He pointed to the frequency with which Pfeiffer's bacillus is encountered in other conditions, and expressed the opinion that there existed many different strains of influenza bacilli.

Lieut.-Colonel F. P. MACKIE, I.M.S., said that the epidemic of influenza in India was widespread and disastrous; millions of people died, whilst in some parts whole villages were wiped out. The reading of bacteriological reports on the subject produced a sense of bewilderment. Bacteriological workers in India had paid special attention to the frequency of Pfeiffer's bacillus and had obtained results similar to those detailed by Dr. McIntosh. The difficulties of working with filter-passing organisms were increased by the instrumental error, particularly the efficiency of filters; the personal factor was also of great importance; the value of the results obtained depended very largely on the technical ability and experience of the worker concerned.

Dr. R. M. BUCHANAN (Glasgow) commented on the marked variability of the conditions known as influenza from a clinical point of view. He recorded an experiment he had performed: a plate of nutrient agar was exposed in front of the mouth of an influenza patient, and Pfeiffer's bacillus, pneumococci, and streptococci all grew in culture. He expressed himself of the opinion that the *Bacillus influenzae* probably played some important part, and that, though the case for the filter passer was strong, it was necessary still to keep an open mind.

Dr. MERVYN GORNON said, in reply, that it was proved conclusively that experimental inoculation with Pfeiffer's bacillus could produce lesions *post mortem* identical with those found in influenza. But was there not some other factor behind it? It was not yet possible to say that the filter passer was the actual cause of influenza, but filter passers ought to be looked for in all cases of common cold and influenza. He explained that he carried out his filtrations under a minus pressure of 10 to 12 cm. of mercury, the operation lasting only five minutes. Small cup-shaped Berkefeld filters worked very well. Undoubtedly a filter-passing organism was present, but what its exact significance was he was not yet in a position to say.

Sir WILLIAM B. LEISHMAN summed up the discussion. He declared that there was a big problem still unsolved; there were many unsatisfactory points about Pfeiffer's bacillus still unexplained. He congratulated Dr. Gordon on the case he had made out for the filter-passing organism, and added that an organized attack on the problem was about to be undertaken by the Medical Research Council, from the filter-passing side, the cultural side, and the chemical side.

THE ACTION OF FLAVINE ANTISEPTICS ON LOCALIZED PYOGENIC INFECTIONS,

WITH SPECIAL REFERENCE TO THE PROCESSES OF HEALING.*

[With Special Plate.]

BY

C. BENNETT, M.B., J. W. S. BLACKLOCK, M.B.,
AND C. H. BROWNING, M.D.

(From the Wards of the Western Infirmary and the Pathological Department of the University and the Western Infirmary, Glasgow.)

So much in the way of prevention of infection has been accomplished by aseptic methods that one is tempted to the conclusion that in dealing with septic conditions, after careful preparation of the operation area, the tissues may be left to combat infection by their own reactive powers. Accordingly it may be judged sufficient merely to protect the parts by means of aseptic dressings from external contamination. Adequate drainage is, of course, the essential requirement in the treatment of all septic conditions, and frequently drainage can be established only by properly directed surgical interference. Consider, for instance, the abscess in appendicitis; when good drainage channels have been made the peritoneum may usually be trusted to deal effectively with the infection. But other parts are much less efficient than the peritoneum in this respect; such is notably the case with the subcutaneous tissues, in which infective processes tend to spread. Here direct attack upon the infective agent by chemical antiseptics is called for. It is reasonable to suppose, and is indeed within the experience of most, that the difficulty of maintaining asepsis on a raw surface is roughly in proportion to the area. Small areas may be neglected, but it is very difficult to maintain a large raw area in a clean state, even if that large area has been produced originally under aseptic conditions. Therefore it is a problem of no small difficulty to combat successfully the infective process on a large area which is already in a septic condition when it comes before the surgeon. As illustrations there are burns, large ulcers, and the areas left after excision of carbuncles. From the treatment of these it is impossible in the present state of knowledge to exclude chemical antiseptics. Every surgeon who deals with large numbers of cases of pyogenic disease has long felt the need of an antiseptic which will fulfil the well-known complementary requirements—namely, maximum effect on organisms and minimum toxic action on body tissues. The powerful antiseptic or "bacteriostatic" property of the compounds of diaminoacridine (flavine antiseptics), together with their relatively low toxicity for mammalian tissues,²⁻⁷ suggested that they might be used

* This work was carried out with the support of the Medical Research Council.

with advantage in the chemotherapy of local pyogenic infections. Opinion in regard to the value of these substances for the prevention of sepsis in contaminated wounds during the late war were practically unanimous,^{10 11 12} and their usefulness in this direction points to a much wider application in many branches of surgery than has hitherto been attempted.^{11 12} Their beneficial action in combating suppuration which has already become established has also been recorded by numerous observers.^{8 9 12 13 14} But as regards their effect on healing observations have ranged from those, for example, of Pilcher and Hull,¹³ who found under the influence of flavine "healthy granulating wounds, over which epithelium is growing naturally," to those of Bashford, Hartley, and Morrison,¹ according to whom "the processes differ in no essential feature from the production of an eschar by a destructive agent not liquefying the tissues." It appears, therefore, that further observations are apposite in regard to the influence of the flavines on healing, as observed in the treatment of suppurative conditions in hospital cases in civil practice. The following report records the results obtained in the daily use of flavine antiseptics (aeriflavine and proflavine—principally the former) over a period of about four years in a series of over one thousand cases under the care of one of us (C. B.). The cases were of such severity as to necessitate their being treated as in-patients.

It would serve no useful purpose to record statistically the number of days or weeks required for healing in individual cases. No two are alike, and, therefore, were a statement as to duration to be made a very minute description of the disease condition would also have to be supplied. Even then the data would be incomplete if the patient's general state were not also detailed. At best it can only be said that healing occurred within a reasonable time or that it was not unduly prolonged. Accordingly, such statistics are omitted in view of the multiplicity of factors which would complicate their interpretation. Tissue was removed from patients at random and submitted to histological examination, the results of which are recorded below. Obviously specimens could not be obtained in even the majority of cases, but those which were taken represent fairly the average conditions met with in the series.*

MODE OF APPLICATION.

Believing that the solution must continuously bathe the infected tissues, the simple method was adopted of soaking ordinary sterilized gauze in a 1 in 1,000 solution of the antiseptic in normal saline and, without wringing, applying it dripping to the part. The dressing was always changed before drying took place. In the early stage of treating an infected surface, when it requires to be "cleaned up," as the common phrase is, the dressing must be changed once or even twice daily whatever therapeutic agent be used. A covering of gutta-percha tissue is not therefore necessary, since there is no time for drying. When the necessity for a daily change of dressing has passed gutta-percha should be employed in order to minimize evaporation. Thus protected the dressing may remain unchanged for two or even three days.

CLINICAL RESULTS.

Before proceeding to discuss the results, the disadvantages attending the use of flavine, which have been recorded by certain workers, will be dealt with. These comprise: (1) encouragement of haemorrhage; (2) the formation of a yellow pellicle on granulating surfaces; (3) delay in healing, which is coincident with pellicle formation; and (4) the occurrence of a rash on the normal skin surrounding a granulating surface.

Encouragement of Haemorrhage (Bashford, Hartley, and Morrison¹). At no time has important haemorrhage been observed from a raw surface treated with flavine, which could not be fully accounted for by causes other than the antiseptic. Minute haemorrhages from the tips of granulations have frequently been seen; the significance of these will be discussed in the section dealing with burns.

Yellow pellicle (Drummond and McNee¹⁰) has never been seen. The absence of this phenomenon has also been commented upon by Pilcher and Hull¹³ in their large series of war wounds. It is of such a pellicle is encouraged by granulating surfaces. On several occasions it was noticed that the dressing on removal was plastered on its deep surface with the exudate of the granulating wound; this doubtless represents the initial stage of the pellicle. Pilcher and Hull have also attributed pellicle formation to evaporation and consequent concentration of the antiseptic.

*The patient's permission was always obtained before a portion of tissue was removed.

Delay in healing, which is associated with the pellicle, has not occurred in any case. In the case of war wounds treated with flavine, apparently by methods similar to that employed here, varying degrees of inhibition of healing have been noted by different observers. Thus Drummond and McNee,¹⁰ Carslaw and Templeton,⁸ and Depage and Maloeus⁹ have interpreted the onset of a stage of inhibition as the indication that flavine had done its work in preventing or overcoming pyogenic infection and that other treatment should then be resorted to. On the other hand, Bashford, Hartley, and Morrison¹ saw from the use of a 1 in 1,000 solution of flavine "very deleterious effects . . . on the entire process of healing, killing successive layers of the reacting tissue elements, including the essential vascular mechanism. . . . The only favourable feature has been that the patient is apparently protected in some way from the absorption of toxic products." It appears unlikely that differences in the commercial flavine products could account for this variety of results, nor have our biological examinations of many commercial samples supported such an explanation.⁵ Owing to the entire absence of such phenomena in the present large series of cases it is impossible to throw much light on the deleterious effects described by Bashford, Hartley, and Morrison. It is possible that war wounds are especially liable to be affected in the manner they describe. But it is clear from the present work, as well as that of Pilcher and Hull,¹³ Ligat,¹² and others, that such evil effects must have been due to complicating factors, and that they are not inseparably attached to the use of flavine antiseptics.

Rash similar to that described by Bashford and his co-workers has been seen in three cases. In these there was a rash of small impalpable spots of a deep red colour, which faded on pressure. In two of these it occurred where gauze saturated with flavine solution was covered with gutta-percha tissue, while in the third case there was no impervious covering. In all three cases the rash disappeared in several days when plain dry sterile gauze was used as the dressing; thereafter treatment with flavine was resumed without reappearance of the rash or any other untoward phenomenon.

The total number of cases in which flavine has been used is over 1,000; but all have been excluded from the present statement in which the antiseptic was not brought intimately into contact with the diseased focus—where, in other words, it might be said that the flavine dressing was only used as a receptacle for discharge. For example, when an abscess was opened by a puncture, this case, because of the small extent of diseased tissue in contact with the dressing, was ruled out. All the remaining 656 cases in the following list developed considerable areas of granulation tissue exposed to the dressing fabric and the antiseptic:

Burns	218
Ulcers of leg	14
Carbuncles	13
Cellulitis	96
Osteomyelitis	77
Acute suppurative bursitis	24
Abscesses (various sites)	120
Septic hands	80
Fistula in ano	14
Total	656

Burns.

Only those in which the true skin was involved are considered here. The healing of superficial burns occurs readily. But the cure of those which granulate has attracted much attention in recent years, as is shown by the number of published methods of treatment. During the first ten days, when the extent of tissue destruction is being determined and sloughs are separating, the surface is dressed daily with flavine solution. When obvious granulations develop the dressing in most cases need be changed only every second day. Burns offer an excellent field for observation of the effect of an antiseptic on granulation tissue and on the growing skin-edge. Destruction of the tips of granulations or the sloughing of considerable areas and delay in the advance of epidermis from the margin were the principal complications for which a watch was kept. Granulation tissue under the influence of flavine has without exception remained healthy throughout. So far is flavine from causing granulations to slough, that small spots of fresh bleeding have often been observed when the gauze was newly removed from the raw surface. This is regarded as an indication that the minute vessels are not damaged by flavine, and that therefore there is a perfect circulation of blood in even the most superficial parts. Such slight haemorrhage would, then, be fully accounted for by the injury to the capillaries when the gauze fabric adhering to the granulation tissue was removed. In this respect a striking contrast is presented to the pale, lustreless surface exhibited when such an antiseptic as carbolic acid (1 in 40 or weaker) is employed. The fact that severe haemorrhage is certainly not encouraged, and possibly even controlled, by the application of flavine is well illustrated by the following case: A woman with

extensive burns of the trunk and lower limbs was kept under treatment in her own home for several weeks. During that time several severe hæmorrhages occurred from the granulating surfaces, until an alarming loss of blood led to the patient being sent to hospital. There the burns were dressed with acriflavine and there was no recurrence of hæmorrhage. Hæmostatic effects have been recorded by others (Carslaw and Templeton¹). There is no delay in the advance of epidermis from the edge; the rate of its growth compares favourably with that under any other form of treatment, as Carslaw and Templeton and others have also observed.

Surfaces for Grafting.

Whether epididymal or whole skin grafts were used it was found that surfaces treated with flavine afforded good ground for their implantation and growth. Any doubt as to the innocuous effects of flavine on the grafts was soon dispelled. It was found that no disadvantage attached to implanting grafts directly on to surfaces in course of treatment with flavine. Thiersch's grafts seem to be quite unaffected by flavine, as has also been noted by Lawson² in ophthalmological practice. They have "taken" quickly in almost every case. In the very few instances in which regrafting was required on account of a first failure there was an obvious reason for the result apart from the antiseptic—namely, the situation, at the point of the shoulder, over the sacrum, and over the trochanter. It was found that the pus-like discharge, which appears after a few days on any surface covered with Thiersch's grafts—the natural result of leaving the dressing unchanged in order that the grafts may remain undisturbed—was reduced considerably and in some cases totally prevented by applying a wet dressing of flavine on the top of the perforated protective tissue covering the grafts. Here a very severe test is imposed on the antiseptic when it is allowed to bath thin shavings of epidermis before they have had time to establish connexion with a new blood supply. Of fifteen cases of grafts actually dressed with flavine fourteen were successful. There were only five cases of whole-skin grafting; the granulating area had been treated with flavine, but the grafts were dressed only with plain sterile gauze. In general, the results were at least as good as in cases which had never been touched by flavine.

Ulcers of Leg.

These were so-called varicose ulcers. Their healing under flavine has been eminently satisfactory. Varicose ulcers in general will, of course, heal under any mild antiseptic treatment if the patient be kept at rest in bed for a sufficiently long time. The need is for a means of shortening that period. With flavine dressings the ulcer develops a clean, bright, red base in from seven to ten days; but in most cases of ulcers large enough to command admission of the patient to hospital oedema must still be eliminated. When the oedema has disappeared grafting is begun. Thiersch's method is, needless to say, very early recurrence being the rule when the patient returns to her usual mode of life. Whole-skin grafting provides a tough covering, which offers a fair resistance to recurrence. As might be expected, however, two or three attempts are sometimes required before the raw surface is successfully covered. That is not surprising in view of the situation and the quality of the tissues.

Carbuncle.

The disease involved the back of the neck in twelve cases and the right shoulder in one. All were treated by excision in the first instance. At the primary operation it is rare that all the diseased tissue can be removed; when the obviously diseased portion is excised there is no means of knowing the extent of the infection which is left behind. Thus it is the rule that acute inflammation continues for some days around the area of excision. Therefore the choice of an antiseptic is of special importance, since the liability to sloughing, which already exists, ought not to be aggravated by the use of any chemical agent which by itself tends to cause necrosis. Under the application of flavine small marginal sloughs continue to appear for several days; these are snipped off. In about eight days there is a clean base. The raw area then begins to contract and healing takes place with that rapidity which observers have frequently noted as characteristic in carbuncular areas. No case has required grafting.

Acute Cellulitis.

In the great majority the disease was in the upper limb, and in many of these the olecranon bursa was involved. Free

incisions were made and large packs of flavine dressing were applied. The results were satisfactory and the duration of the disease was certainly not longer than would have been the case had other antiseptics been used. It was distinctly noticeable that the epidermis did not show maceration, and any sloughing that occurred could be accounted for by the virulence of the infective process, since it took place only in those areas in which sloughing was threatening before treatment was begun.

Septic Hands.

This loose term comprises all degrees of pyogenic infection about the hand, from involvement of part of one finger to that of the whole hand with extension to the forearm. The septic hand is a problem by itself, and, probably more than any other condition in the surgery of pyogenic disease, illustrates the need for efficient drainage. Drainage must be followed by antiseptic treatment. When carbolic acid was used there was the constant risk of resulting gangrene of the finger-tips. With flavine there is, of course, no such danger. Healing has been invariably good, and although carefully sought for no complications attributable to flavine were discovered.

Acute Bursitis.

In all of these cases the prepatellar bursa was affected. Suppuration had extended considerably beyond the limits of the bursal membrane, as is the rule in the type of case which reaches hospital. Consequently wide incisions were necessary and gaping wounds remained to be treated. Experience in cases of this kind treated with various antiseptics has indicated that healing is slow. With flavine the purulent discharge disappears in a few days, and in ten or twelve days bars of good granulation tissue are formed. The total duration of treatment is reasonably short if the skin is now undermined and secondary suture performed.

Abscesses.

Only those which required large incisions are noted here. Healing was reasonably rapid.

Fistula in Ano.

After operation the track was dressed with gauze soaked with flavine solution, which was changed frequently. Further trouble from infection of the wounds by faecal matter was not observed.

Osteomyelitis.

The cases were of the acute hæmatogenous type occurring in childhood or adolescence. They were dealt with on standard lines, which may be described as follows, for instance, where the tibia was affected. The necessary amount of bone was gouged out, and the gutter was sluiced with some bland sterile fluid to wash away pus and fragments of bone and other tissue. The cavity was then packed with gauze soaked in flavine solution, and over the packing a large amount of the same dressing was applied. This was not changed for at least forty-eight hours, lest recurrence of gross hæmorrhage should be encouraged by the disturbance. The operation is exhausting, and the loss of blood is sufficiently serious without adding to it by further hæmorrhage caused by disturbance of the dressing. It is important to note that in the cases treated with flavine no hæmorrhage worthy of mention occurred. The cavity at the time of the first change of dressing appeared practically as at the operation. The dressing was then changed daily. It was found that granulation tissue rapidly covered the walls of the gutter, and occasionally some minute hæmorrhages from the tips of granulations appeared at the change of dressing, as has been already noted in the case of burns. The gutter became filled with granulation tissue at a reasonably rapid rate, and if diseased bone had been judiciously removed healing was completed in at least the average time. The effect of the antiseptic on new bone developing from the carefully preserved periosteum was studied attentively. It was soon clear that no harmful effect on the process was attributable to the flavine. The periosteal granulation tissue stiffened in a few days with osseous deposit, and thereafter regeneration of bone advanced steadily.

DURATION OF TREATMENT.

The application of flavine has been continued in the present series of cases until the stage was reached at which it is safe to employ merely an inactive, sterile dressing. Flavine was employed therefore in individual cases for varying periods, frequently up to three months. In no instance was it found

necessary for any reason to substitute any other antiseptic—for instance, because the infection failed to be overcome or because healing was in abeyance.

HISTOLOGICAL OBSERVATIONS.

Tissues were fixed in Zenker's solution usually within a few minutes after excision. Material from twelve cases was examined; these comprised burns of the third degree, carbuncle, cellulitis, osteomyelitis, and recurrence of scyris in an old healed compound fracture. Inasmuch as the process of formation of granulation tissue and healing of epithelium occurred in uniform fashion throughout the series of over 600 cases, the dozen whose histology was investigated may be taken as fully representative of the behaviour of such wounds under continuous treatment with acriflavine or proflavine.

Granulation Tissue.—This shows the usual constituents, without significant abnormality either of a qualitative or a quantitative character (Figs. 1, 2, and 6). (In the depths conversion into more mature fibrous tissue is observed.) It is noteworthy that the embryonic capillary blood vessels as a rule extend right up to the surface, and there red blood corpuscles may be seen within their lumina (Figs. 2 and 6). This agrees with the clinical observation that in cases treated with flavine when the dressing is removed there is a tendency for minute oozings of blood to occur. Further, mitoses have been found repeatedly in the superficial layers. On the surface of the granulation tissue there is frequently an exudate of polymorphonuclear leucocytes of a few cells in depth (Fig. 4). Organisms, if present in it, are so scanty that they failed to be found on microscopic examination of eleven of the twelve cases in sections stained by Gram's method and by thionin-blue. An interesting observation was made with regard to the staining of this layer of leucocytes; it was found that in sections stained with haemalum and eosin the leucocytes, especially at the free surface, might show poor nuclear staining, and the cells appeared necrotic and disintegrating (Fig. 3). However, in sections of the same tissue which were stained with eosin and methylene-blue, all the leucocytes showed well-stained, clearly defined nuclei (Fig. 4). The significance of this striking difference of behaviour toward the two reagents is not clear, but it indicates that caution must be employed in interpreting appearances of morphological degeneration. Small haemorrhages, when present, could justifiably be attributed to manipulative trauma. In some cases minute isolated deposits of fibrin, intensely eosinophile and retaining the violet stain by Gram's method, are present amid the layer of leucocytes, and sometimes they extend for a short distance into the granulation tissue. This, no doubt, is the microscopic rudiment of the pellicle of certain observers.

Epithelial Regeneration.—In some instances the epithelial margin showed that thinning out which is generally accepted as evidence that the cells are in process of covering the granulation tissue (Fig. 5). Clinical observation has demonstrated that the ingrowth of epithelium proceeded without interruption under the application of flavine; hence other microscopic appearances of the epithelial edge must not be interpreted as evidence of delay or inhibition of its growth. Thus an abrupt, relatively thick edge has been repeatedly seen in cases in which extensive epithelial ingrowth had already taken place and in which this growth continued to progress without interruption subsequently (Fig. 6). The absence of elastic fibres from the subepithelial tissue, as demonstrated by Weigert's method, afforded further confirmation that a region of newly formed tissue was being dealt with.

SUMMARY.

The results are recorded of a series of over 600 severe burns and pyogenic conditions treated in hospital wards continuously with flavine antiseptics (acriflavine or proflavine) by a simple method. The points specially investigated have regard to the rate and progress of formation of granulation tissue, ossification, and healing of skin epithelium. Only those cases are considered in which intimate contact of the tissue with the antiseptic occurred. As compared with other methods of treatment, there was clinically no interference with formation of granulation tissue. There was no evidence of pellicle formation or necrosis. There was no tendency to haemorrhage beyond the slight oozing which occurs from the tips of well-vascularized granulations denuded of their surface in the act of changing dressings and which is to be regarded as evidence of their healthy state. Ossification proceeded actively in periosteal granulation tissue under

application of flavine. Epithelial regeneration, both in the form of ingrowth for rafts proceeded actively in solution. Histological unselected cases have confirmed and supplemented the clinical observations.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF INTERSTITIAL GESTATION.

THE whole history of the following case—amenorrhoea, passing of blood and decidua, and somewhat sudden onset—pointed even from the first to extrauterine gestation, but it was manifest that nothing short of abdominal exploration could possibly have revealed the exact cause. Interstitial pregnancy is very rare. Personally, I have only seen one other case, so that the unusual features of this one made it appear worthy of record.

On May 31st last I was asked to see Mrs. R., aged 29. She complained of pain in the left iliac fossa, and told me moreover that she was two and a half months pregnant, having had her last period on March 15th. During the night she had passed some blood and membrane per vaginam, the latter having every appearance of decidua. The previous menstrual history was quite normal, and she had had one child. On examination the temperature was 102° F., pulse 120, whilst the abdomen was rather tender over the left iliac fossa. On examination the uterus was found to be enlarged to about the size of an eight to ten weeks' pregnancy. There was nothing to be felt on either side of the womb to suggest ovarian or tubal trouble. I concluded that an abortion was threatening. Twenty-four hours' administration of ergot had no effect, so I admitted her to the Royal Hospital on June 2nd. The next day I examined Mrs. R. under an anaesthetic, dilated the cervix fully so as to admit the index finger, and was rather surprised to find she was not pregnant at all within the uterus. I removed some adenomatous tissue with a blunt curette and again examined the patient, with negative result. My colleague, Mr. R. Massie, who happened to be in the operating theatre at the time, examined her at my request, and agreed with me that beyond the enlargement of the uterus there was no swelling or tumour to be felt. The patient was then put back to bed. On June 4th and 5th her temperature was 99°, and she was fairly comfortable. On the evening of the 6th she began to complain of severe pain on the left side and generally over the pelvic region. The temperature rose to 104° and she had a severe rigor, and again the next morning with the temperature 105°. I saw her at 12.30 p.m. and she appeared very ill. I examined her per vaginam and found that she was extremely tender on the left side, and the left Fallopian tube seemed swollen. It was obvious that the patient was suffering from a very acute pelvic infection affecting the abdominal cavity, so I decided to operate at once.

Operation.—On opening the abdomen in the mid-line, I found the uterus enlarged, and in the left cornu was a cystic swelling, purple in appearance, from which was oozing, through a very small hole, some dark brown fluid. Both ovaries were perfectly healthy, as was also the right Fallopian tube and the distal four-fifths of the left one. On opening up the tumour bleeding was profuse. As the patient's condition was critical and the escaping fluid causing severe toxæmia, I decided to perform a supravaginal hysterectomy. At the close of the operation I inserted a rubber drainage tube at the lower end of the incision down into the pelvic floor. The patient is making an excellent recovery.

On examining the removed uterus, I found the whole organ perfectly normal except for the tumour, which was about 2½ inches in diameter, and situated four-fifths in the left cornu of the uterus itself, the other one-fifth involving the isthmus of the left Fallopian tube. There appeared to be no connexion between the uterine cavity and the tumour, but there was between the Fallopian tube and the sac. The tumour itself contained chorionic villi, but no embryo was visible. It was of the size of a three to four weeks' gestation, which had gone on to molar formation.

JOHN W. HEEKES, M.B., B.S. (Lond.),
Surgeon, the Royal Ho

Rebichus:

NEUROLOGICAL PROBLEMS OF THE DAY.

A SERIES of lectures printed exactly as they were delivered to the Faculty of Medicine in Paris have been published in a volume with the title, *Questions Neurologiques d'Actualité*,¹ which may be translated, "Neurological problems of the day." They form a volume of the greatest value to the student of neurology. Each of the twenty lectures is from the pen of an acknowledged authority on the subject. Such a collection of monographs provides the reader with the personal views of the writers, as well as with a summary of the recent facts as to many different neurological problems. Within the limits of a review it is impossible to describe in full or to criticize in detail the manifold matters of interest discussed.

A graceful tribute has been paid to the British school of neurology by making the volume open with Dr. Kinuier Wilson's lecture on progressive lenticular degeneration and allied conditions. After reporting, with clinical details, two new cases of the disease which bears his name, the author proceeds to discuss the pathological anatomy and the pathogenesis; it is interesting to note that he is careful to distinguish the disease from pseudo-sclerosis, and to point out the analogies on grounds of morbid anatomy between progressive lenticular degeneration and such conditions as subacute combined degeneration of the cord and pellagra. The physiology of the condition, especially in relation to the involuntary movements, is only briefly discussed.

Dr. Chutein's lecture on cerebral tumours is a useful general account of the subject. Important and valuable though it be to emphasize the danger to vision involved in delayed surgical interference, we cannot agree with the statement that in a patient who is the subject of a cerebral tumour the visual acuity will remain what it was at the moment of surgical intervention. Localizing signs are described very shortly, too cursorily, in fact, for this section of the lecture to possess any very great value. Though the effect of tumours of the temporal lobes on the optic tracts are mentioned, we find no reference to the important changes in the visual fields which have been found in such cases, and the author seems to us to exaggerate the diagnostic value in cerebral tumour of changes in the cerebro-spinal fluid. The statement that cerebral abscess is rarely accompanied by any intense symptoms of hypertension is rather too sweeping for general acceptance.

In the third lecture Dr. Claude deals with intracranial hypertension and gives in addition a very valuable account of serous meningitis and pseudotumor cerebri. In the etiology of the condition he lays stress on the part played by infections, especially those of the middle ear. His views as to the compression of the hypophysis by serous meningitis can less readily be accepted, and we may be permitted to doubt the frequency of a secondary endocrine defect from this cause. His remarks on treatment are excellent and full of details of practical value.

Dr. Roussy contributes the fourth lecture, on disturbances of sensation from cerebral lesions; here we are pleased to find a full acknowledgement of the valuable work of Head and Holmes. Beginning with an excellent summary of our present knowledge of the thalamic syndrome, Dr. Roussy goes on to give a very interesting account of the disturbances of sensation in lesions of the parietal lobes. In this connexion he lays stress on what he calls the longitudinal or radicular distribution of the sensory loss present in some cases; recent observations on this point would appear to recall the views expressed by Horsley a good many years ago.

A longer chapter on traumatic lesions of the spinal cord by Dr. Guillaumin follows. In general it may be regarded as an adequate presentation of a subject on which so much has recently been written; our knowledge of it has been much advanced by the losses of the war. Many points of great practical value to the clinician are fully discussed, especially in regard to diagnosis; theoretical physiological questions are avoided, and we could perhaps have wished for a slightly fuller account of the phenomena of spinal automatism.

In the restricted space at his disposal Dr. Lhermitte gives a good general description of lethargic encephalitis; it is to

be regretted that little mention is made of the sequelae, and that the whole domain of the mental symptoms is neglected. Dr. Souques's lecture on the Parkinsonian syndromes is wholly good, the usual chronic variety and that due to the virus of lathargic encephalitis being both fully discussed. A good but brief account of the anatomical connexions of the corpus striatum is a valuable addition.

Dr. Babonnicx's description of the infantile encephalopathies is clear and concise, but it would have been well if the author had given some clinical details of the case of mongolian idiocy, a reproduction of whose brain is figured showing a gumma in the cerebral meninges; the reader is left to infer that this lesion was the cause of the mongolism, a view to which few could be found to assent. Dr. Léri's account of the muscular atrophies of syphilitic origin is very valuable and instructive, for the frequency of a syphilitic basis in such conditions as amyotrophic lateral sclerosis, for example, is only now beginning to be generally recognized.

In Dr. Sauton's remarks on exophthalmic goitre the reader will find many opinions expressed which differ from those generally accepted in this country. Thus few here would be inclined to assign so important a place to tubercle and syphilis in the etiology as he appears to do; again, we are surprised to find that in the account of the circulatory symptoms no mention is made of auricular fibrillation—surely an unfortunate omission.

The lecture by Dr. Sicard on the neuralgias and their treatment is a very clear, albeit somewhat dogmatic, account of a difficult subject. His practical lessons in diagnosis and treatment, however, may be heartily praised, although we cannot quite agree with his optimistic views as to the treatment of causalgia by alcoholic injections into the affected nerve trunks.

Of the remaining lectures those of changes in the pupils by Dr. Poulard and on spinal automatism by Dr. Foix are perhaps the most valuable. In the former we note the statement that the author has only met with the Argyll Robertson pupil in cases of syphilis of the central nervous system; there are, however, now on record a considerable number of cases in which this disease was not present and where some other pathological cause was clearly established.

Professor Pierre Marie concludes the volume by a brief but lucid summary of the subject of aphasia, in which he maintains his own now well-recognized views against the older and more classical conceptions.

It is hardly possible within any reasonable limit of space to do full justice, either by way of praise or criticism, to this volume. It can certainly claim to be a most interesting and valuable account of some of the more difficult and absorbing neurological problems of the day.

THE SMOKELESS CITY.

THE lay as well as the medical reader cannot but be attracted by a book entitled *The Smokeless City*,² written jointly by the Lord Mayor of Manchester and an Associate of the Sanitary Institute, with a preface by the Chairman of the Departmental Committee on Smoke Abatement, and presented in an art wrapper at the moderate price of 1s. 6d. The reader will not be disappointed in its contents; it is a credit to all who have contributed to its production, and is marked throughout as well by intimate scientific and practical knowledge of the subject as by full appreciation of the difficulties of getting the British house-builder and household to give up even in part his fondness for an open coal fire.

Knowledge and moderation characterize the book from beginning to end. The value of sunlight as a health agency is referred to, and it is pointed out that though factory smoke is largely being brought under control, domestic pollution of the atmosphere is even more important in respect alike of cleanliness and economy. The present methods of obtaining heat in dwelling houses are criticized, and it is noted that this country has lagged far behind all others, partly owing to cheapness of coal—a factor which has for the time departed, probably never to return. Much regret is expressed that the Ministry of Health has not so far taken anything like sufficient advantage of the opportunity afforded by rate- and State-supported housing schemes to require scientific methods of heating, or to give due effect to modern knowledge of the subject, and in concluding his preface Lord Newton asks

¹ *d'Actualité*. Twenty lectures given at the Paris, 1921. With introduction by Professor Sauton et Cie. 1922. (Med. 8vo, pp. vi + 551; 1s. 6d.)

² *The Smokeless City*. By E. D. Simon, M.I.C.E., M.I.M.E., and Marion Fitzgerald. London: Longmans, Green and Co. 1922. (Demy 8vo, pp. ix + 82. 1s. 6d.)

where is the logic of spending millions of money on so-called social reform "if this particular nuisance, expensive, unnecessary, and offensive, is to be permitted to continue unchecked." He answers his own question by saying that we are only just awakening to the fact that existing conditions are discreditable to a highly civilized community, though Sir Alfred Moud has the honour of being the first Minister to do his obvious duty in the matter.

As regards action which ought to be taken now by owners and occupiers, the authors devote useful and practical chapters to house warming, hot-water supply, cooking, and low temperature fuel. In doing so they discuss, in thoroughly competent fashion, radiation and convection, alleged "drying of the air," ventilation in relation to heating, slow combustion grates, gas fires, electric heating, central heating, and, in fact, every relevant question. They strongly recommend gas fires for most purposes, though not for hot-water supply, and they hold that the popular belief that gas heating is dangerous is "due to a newspaper stunt, and, like many such stunts, is untrue." At the same time they advise that at present one or two coal fires should be made possible in a moderately sized house, so as to avoid failure of reform by insisting on revolution. The importance of the subject for Manchester in particular is illustrated by the story of an M.P. who had an engagement to speak there, and, not feeling well, went to see a doctor as to whether he should risk the visit. The doctor replied: "Manchester? Certainly not. Nobody is well enough to go to Manchester." *The Smokeless City* is an excellent little book, and should be a valuable agent in attaining the object to which it is devoted.

DORLAND'S MEDICAL DICTIONARY.

We have received the eleventh edition of the *American Illustrated Medical Dictionary*,³ by W. A. NEWMAN DORLAND. The fact that the first edition saw the light in 1900 and that the editions are now nearly in their teens is sufficient proof that there is a constant demand for this very useful book. We do not envy the compiler of such a dictionary as this his almost Sisyphean task, for he is aware that, while an edition is still in the press, more terms are being coined by the restless workers in medicine and the allied sciences, and that to be of real value his work must be up to date. He therefore cannot rest, but must be for ever collecting and arranging these terms. This edition, we are told in the preface, contains several hundred new definitions, "most of which are not to be found in any other dictionary." The additions have been most numerous in the fields of biological chemistry, endocrinology, immunology, and neurology, though every branch of medical science has received its share of new terms. Among the valuable features of the work are the lists of micro-organisms, diseases, tests, operations, syndromes, etc.; the list of bacilli alone fills more than nine pages, and this in spite of the utmost condensation compatible with clearness. There are also many illustrations and plates, "chosen for their practical value in aiding the text rather than for their pictorial beauty."

In the search for new terms we looked in vain for "*Spiroplasma pallidum*," the designation adopted by the Medical Research Council for the pathogenic organism of syphilis. We did, however, find "vitamin," with the alternative spelling "vitamine." As there appears to be no reason for adding the final *e*, and as the spelling first given is that generally accepted, it would perhaps be well if in future editions no alternative were given. The question of the final *e* in many words—for example, adrenalin, aniline, purine, etc.—is a very vexed one, and those engaged in passing for press collections of papers by various writers, such as those contained in this JOURNAL, are often much put about by the personal idiosyncrasies of the authors. American writers, we believe, as a rule take the short way and leave out the *e*—though we note that Dorland allows "purino" as an alternative spelling. We in England—or at any rate those who go to some pains in this matter—are largely governed by the rules laid down by the Chemical Society, which state that basic substances should invariably be indicated by names ending in *ine*, the termination *in* being restricted to certain neutral compounds.

The book is beautifully printed, on very thin but sufficiently

opaque paper (the twelve hundred odd pages with covers form a volume less than two inches in thickness); in its flexible leather cover it is a pleasure to handle, and for its size is wonderfully complete. Dorland has for years been used in this office as a reference book, and it has rarely been consulted in vain. It may confidently be recommended to practitioners and students in need of a dictionary of moderate size.

ANNALS OF MEDICAL HISTORY.

THE spring number of the fourth volume of the *Annals of Medical History*⁴ bears on the cover the portrait of Yelpean, who was an ornament of the French school of surgery during the reign of Louis Philippe when Paris, with its thirty hospitals and five thousand medical students, was the medical Mecca; Dr. J. Chalmers Da Costa gives thumb-nail sketches of the giants of that day, and mentions that Dupuytren, who was a kind of emperor of surgery, annihilated Meillier's contention that inflammation in the right iliac fossa started in the vermiform appendix rather than in the caecum, and thus kept the clock back for fifty years. Most appropriately Dr. J. H. Gibbon of Philadelphia provides a companion account of London surgery in the early part of the nineteenth century, dealing first with the outstanding personality of Sir Astley Cooper who, like Abernethy, was a pupil of Dupuytren, Desault, and Lisfranc in Paris; he is described as the great practical surgeon of his day as contrasted with its great scientific exponent—Abernethy. Professor David Riesman writes on the influence upon American medicine of the Dublin medical school—Graves and Stokes, who are regarded as in large measure responsible for the popularizing of the stethoscope both in Britain and in America. Dr. W. S. Middleton describes the life and works of the great and gentle anatomist, Caspar Wistar, junior, whose memory is kept green by the Wistar Institute in Philadelphia and more familiarly by *Wistaria speciosa*, written Wisteria by the botanist Nuttall, who named it. In an authoritative article extending over sixty-three pages Knud Faber, Professor of Internal Medicine in the University of Copenhagen, traces the progress of nosography, or the systematic description of disease in modern internal medicine, commencing with Sydenham and the nosologists, and then discussing successively the anatomical, physiological, bacteriological, and functional eras. In his final section on constitutional pathology he remarks that the most recent advance in nosography, which is almost entirely a growth of this century, is directly associated with the influence exerted on pathology by modern research on heredity. In a short article Dr. Jacob Rosenbloom deals with the history of pulse timing and refers to Sir John Floyer and his physician's pulse watch. The editor contributes a number of interesting notes, and there are reviews of recent works on medical history.

NOTES ON BOOKS.

THE new number of *Brain*⁵ forms the first part of the forty-fifth volume; it bears the name as editor of Dr. GORDON HOLMES, who recently succeeded Dr. Henry Head in that capacity. It contains a paper on Thomsen's disease, by Dr. J. Rosett of Columbia University; a contribution to the anatomy of spina bifida, by Dr. Violet H. Keiller of the University of Texas; observations on cerebellar stimulations, by Drs. F. R. Miller and F. G. Banting, from the Department of Physiology of the Western University Medical School, London, Canada; a report of three cases of supra-pituitary tumour presenting Fröhlich's syndrome, by Dr. Charles N. Armstrong, from the National Hospital, Queen Square; and a paper on the nervous control of the urinary bladder in amphibians, by Mr. F. J. F. Barrington, from the laboratories of the Surgical Unit, University College Hospital Medical School.

We have received for notice the May number of *Surgery, Gynaecology, and Obstetrics*,⁶ incidentally the official organ of the American College of Surgeons. This journal is probably well known to our readers, for on its first appearance some years ago it achieved instant popularity owing to its excellent format. The fine reproduction of illustrations has always been an especial feature of this periodical, and this, with its thick glossy paper and clear print,

⁴ *Annals of Medical History*. Edited by Francis R. Packard, M.D. Spring number, May, 1922. Vol. iv, No. 1. New York: Paul P. Hoeber. (Pp. 1-113; yearly subscription 8 dols., single numbers 2.50 dols.)

⁵ Macmillan and Co. Price per part 6s. net. Yearly subscription 24s. net.

combino to give it a handsome appearance, at that time distinctly in advance of anything that we had in this country. Even to-day its illustrations compare very favourably with our own beautiful *British Journal of Surgery*. The May number contains a study of a case of intracranial cholesteatoma successfully removed by Harvey Cushing. An article by J. O. Polak follows on the abuse of the operation of Caesarean section. A. H. Bizarro reviews a fine series of 123 cases of carpal fractures; whilst amongst several other contributions may be mentioned a paper by Ott on cranial nerve palsies produced by tumours in the region of the jugular foramen, a paper on adult megacolon by Fowler, and a paper by Trouton on the subsequent history of the breast remaining after radical amputation of its fellow for carcinoma. An important feature of this journal is its "International Abstract of Surgery," which embodies summaries of the more important articles appearing in the European and American press. These abstracts are very full, and are sometimes illustrated, to the reader's great profit.

"SIXTY-FOUR YEARS A DOCTOR."

Correction.

OUR attention has been called to an error in the review of this book published last week. On page 272, half-way down the first column, we say: "Again, with reference to a case of appendicitis (this in December, 1886)." The date should be December, 1883. As Sir Charles Brown says, there were no operations then for appendicitis, but in 1886 there were, and if the case referred to had happened at the later date the patient would have been operated on, instead of having to use an infusion of common shag tobacco.

The price of Mr. Muirhead Little's *Artificial Limbs and Amputation Stumps*, published by Messrs. H. K. Lewis and Co., Ltd., of London, is 18s., not 18 dollars, as by a clerical error was stated last week.

ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS, 1921.

IN the Annual Report of the Chief Inspector of Factories and Workshops for 1921 the method of dealing with the year's work under sectional headings has again been adopted. A marked feature of the publication is the complete absence of superfluity, the impression conveyed being rather that the editor must have been at some considerable trouble to decide what might conveniently be left out. Every item of information given is of value and could not fail to prove useful to any reader, medical or other, who takes an interest in the health, safety, or well-being of those engaged in industrial occupations. As is usual, there is much in the contents of special interest to the medical profession:

The serious depression in trade, as might be expected, materially affected the statistics for the year. The examinations for the certificate of fitness dropped down from 403,660 (1920) to 221,536, medical examinations under special rules and regulations from 225,678 to 175,735, accidents from 138,702 to 92,565, and prosecutions from 1,081 to 573. Food manufacture (particularly sugar confectionery) and the textile machinery branch of engineering are the only trades which were doing any real business. It is curious to note, however, that in spite of these adverse factors the gradual evolution in industrial methods has not stopped; factories increased during the year by 2,685, whilst workshops diminished by 4,944, and there are records of the establishment of greatly improved processes of manufacture, particularly in steel industries. Owing apparently to the institution of a special engineering branch of the inspectorate, it has been found possible to devote a considerable amount of attention to a survey of safety measures and to improving the working of dangerous trades regulations. Combined efforts of this new branch and of the medical branch were directed particularly to the dust problem, and it would appear that some headway was made in devising closed automatic and semi-automatic processes and the improvement of local exhaust ventilation. There seems to be a fairly general opinion that the most frequent and undoubtedly the most annoying stumbling-block to real progress in preventive measures is a combination of the constitutional carelessness of the worker and the undoubted failure of the average employer to realize that the "spirit" equally with the "letter" of a regulation demands a conscientious observance. Some of the details given of what pure want of thought and attention can lead to are really astonishing. Dr. E. L. Middleton examined clinically the lungs and upper air passages of 1,000 workers engaged in metal glazing, grinding, and dressing, and when he has got through another 400 hopes to publish information of value on the medical aspect of the question. The nature

and amount of dust given off in these processes is also being closely investigated, and Dr. Middleton made special inquiry into the incidence of silicosis amongst workers in refractory materials in places not coming under the Refractories Industries (Silicosis) Scheme, 1919, and also into the working of the medical arrangements in cases which do come within the scheme. The number of cases of lead poisoning recorded was 230; there were 23 deaths, but the general severity is reported to be below the average. A number of exceptional cases occurred in the cutting of steel plates on old warships by the oxy-acetylene flame owing to the volatilization of lead from the painted surfaces. From the analysis made, Dr. Legge estimates that a cutter doing this work inhales 18 milligrams of lead daily, or 16 milligrams in excess of the amount which can be inhaled without producing poisonous effects. It was also found that some of these cutters suffered from symptoms of "brass-founders' ague" through the lighter plates being galvanized. On the research side investigations have been reopened with a view to find out the exact diagnostic value of basophilin in cases of suspected lead poisoning.

Reference is made to the International Labour Conference in Geneva, which resulted in the adoption of a draft convention prohibiting, except under certain special circumstances, the use of white lead and lead sulphate in paints applied to interiors of buildings and regulating the use of these for other purposes. As regards anthrax, the Conference appointed a committee to study the subject in all its bearings, but particularly with a view to find out some means of eradicating the disease among animals. Reference is made to the successful treatment of East Indian goat hair and Egyptian wool and hair at the Anthrax Disinfecting Station, and also to the possible closing down of the establishment for financial reasons. Attention is drawn to the importance of requiring persons suffering from carbon monoxide poisoning to rest and not to walk about. Particulars are given of a series of investigations made by Dr. Henry on the effects of naphtha fumes and on aniline black dyeing processes. The seriousness of chrome ulceration is demonstrated by particulars collected from twenty-five dyeworks, which show that a total of 130 cases involved 1,144 weeks of lost time.

Dr. Legge devotes a considerable amount of space to certificates of fitness. He specially draws attention to the revision of particulars respecting disease and bodily infirmity supplied by the surgeon in his annual report, and states that the alteration was decided upon as a result of a representation from the Association of Certifying Surgeons pointing out that Section 122 (6) of the Factory and Workshops Act, 1901, asked for a report not on rejections alone but "as to the number of persons inspected during the year and the results of the inspections." As it was late in the year before the certifying surgeons principally concerned could be notified and take the necessary steps to collect the required information, Dr. Legge is of opinion that only about half the particulars respecting disease and defects requiring conditional or advisory certificates have been supplied. He has, however, considered it advisable to publish the table, which now provides a well-thought-out classification of the diseases and bodily defects found, and shows the number under each heading qualifying for rejection and for conditional certificates respectively. In spite of its incompleteness, out of a total of 15,689 requiring rejection or conditional certificates, 10,640 are recorded as having been dealt with on medical grounds, and 1,266 for unsuitable attire (including loose hair). It is noted that, although many occupiers are taking an increased interest in medical supervision, there is unfortunately a tendency to replace payment of the surgeon by contract by payment at piece-work rates. This is apparently regarded as bad policy, for the reason that "a contract enables certifying surgeons to do really good work in periodic examinations apart from that required by the law, to give advice and actually to supervise the work of first aid."

A definite opinion is expressed on the desirability of more co-operation among certifying surgeons and greater uniformity both in examinations and in dealing with defectives, and a strong point is made of the advantages to be derived from co-operation with welfare supervisors and nurses. As regards welfare work it is stated that reports from all over the kingdom show that this movement has held its own in face of the adverse circumstances of the times, and certain new orders have been issued during the year. A separate chapter deals with underground workrooms in London, and an excellent article on health and sanitation shows how much has still to be accomplished.

CURRENT NOTES.

Alteration in Terms of Service of Insurance Practitioners by "Order of the Minister."

It will be recalled that, at the time of the reduction of the insurance capitation fee at the beginning of this year, considerable apprehension was caused amongst insurance practitioners by the action of the Ministry in introducing the new fee as from January 1st, having regard to the fact that three months' notice of the intended change had not been given to individual practitioners. The question was taken up with the Ministry, who contended that, three months' notice of a change having been given to the negotiating body on behalf of Panel Committees (that is, the Insurance Acts Committee of the Association), individual notice of such change was not necessary. The Ministry further stated that the fact that the Central Pool, out of which insurance practitioners are paid, was each year constituted by an Order of the Minister, was also a reason why individual notice was not necessary. The Insurance Acts Committee had not previously heard of the existence of an "Order of the Minister," and the Ministry was asked the extent of the powers vested in the Minister which rendered possible modifications of the conditions of insurance practice by such an Order, and, therefore, without requiring, in accordance with paragraph 2 of the Terms of Service, that three months' notice of the proposed modification should be given to individual practitioners. A list of the matters on which the Minister is at present empowered by Regulation to take action modifying the conditions of service throughout the country has been furnished by the Ministry. The Ministry was also asked for an assurance (similar to that already given in connexion with Orders in Council) that, in the event of any alteration proposed to be made by Order of the Minister, three months' notice thereof will be given to the Insurance Acts Committee, and that previous opportunity for discussion will be afforded whenever possible. The following reply has been received:

Ministry of Health, Whitehall, S.W.1,
July 27th, 1922.

Sir,
In reply to your letter of the 11th inst. . . the Minister desires to give the definite assurance that he will, before making an Order which affects the terms of service of insurance practitioners, discuss its provisions with the Committee representing the Panel Committees of the country, and will, after the Order has been made, give to the individual practitioner the fullest notice of its provisions which the national exigencies permit.

I am to add that, although the period of notice given to the representative Committee will not in the ordinary course be less than three months, it is essential that the Minister should retain power to deal by Order with possible emergencies, and it is believed that your Committee will appreciate that serious disadvantages, both to the medical profession and to the insured population, might arise if the terms of the assurance for which the Committee have asked were such as to render it impossible in emergency to intro-

duce by Order modifications of the terms of service, which might be urgently required, within a period of less than three months. In no case, however, will these emergency powers be exercised without prior consultation with your Committee.

I am, Sir, your obedient Servant,
(Sgd.) L. G. Brock.

The Secretary, Insurance Acts Committee of the
British Medical Association.

Socialization of Hospitals: Resolution of the Social Democratic Federation.

The resolution passed at the Annual Conference of the Social Democratic Federation pressing for the immediate socialization of the hospitals in the services of the nation will not, we are sure, find favour with the public generally. State contributions must inevitably lead to State interference with the independent and voluntary management which the Representative Body maintains is the essence of the voluntary system in this country. The resolution above referred to is in reality a counsel of despair, and none of those who have the true interests of the voluntary system at heart are likely to be influenced by the clamorous advocates of nationalization. We believe that the public desires the continuance of the present system; and therefore it is for the public to show by its generous support that where there is a will there is a way.

Association Notices.

FURTHER EXTRAORDINARY GENERAL MEETING.

A FURTHER Extraordinary General Meeting of the British Medical Association was held at the Head Office, 429, Strand, London, W.C.2, on Tuesday, August 15th, 1922, at 2.30 p.m., when Dr. H. B. Bradkenbury, Deputy Chairman of the Representative Body, was in the chair.

The Solicitor explained the reason for which the meeting had been called and the necessity for the Resolutions passed at the Extraordinary General Meeting held in the Bute Hall at the University of Glasgow on Friday, July 21st, 1922, being confirmed by the members present.

The proposed alterations in the Articles of Association were then submitted by the Chairman *serialim* and were unanimously approved and confirmed.

PROPOSED AMALGAMATION OF MID-ESSEX AND NORTH-WEST ESSEX DIVISIONS.

NOTICE is hereby given to all concerned of a proposal made by the Council of the Essex Branch for amalgamation of the Mid-Essex and North-West Essex Divisions of the Essex Branch, the new Division to be known as the "Mid-Essex Division."

The matter will be determined in due course by the Council. Any member affected by the proposed change and objecting thereto is requested to write, giving reasons therefor, to the Medical Secretary, 429, Strand, London, W.C.2, not later than September 19th, 1922.

British Medical Association.

COUNCIL AND COMMITTEES FOR 1922-3.

COUNCIL.

Ex officio.

- Dr. R. A. Bolam, LL.D., Newcastle-upon-Tyne, *Chairman of Council*.
 Sir William Macewen, C.B., LL.D., M.D., F.R.C.S., F.R.S., D.Sc., Glasgow, *President*.
 Dr. R. Wallace Henry, Leicester, *Chairman of Representative Body*.
 Dr. G. E. Haslip, London, *Treasurer*.
 Professor David Drummond, C.B.E., M.A., D.C.L., Newcastle-upon-Tyne, *Past-President*.
 C. P. Childs, Esq., F.R.C.S., Southsea (Portsmouth), *President-Elect*.
 Dr. H. B. Brackenbury, London, *Deputy Chairman of Representative Body*.

Twenty-four Elected by Branches in United Kingdom.

England and Wales.

- Dr. H. S. Beadles, London.
 Dr. H. C. Bristowe, Wington, Somerset.
 Dr. C. Buttar, London.
 Dr. Rt. Hon. Lord Dawson of Penn, K.C.M.G., G.C.V.O., C.B., M.D., London.
 Dr. James Don, Newcastle-upon-Tyne.
 Dr. T. W. H. Garstang, c/o B.M.A., London.
 N. Bishop Harmau, Esq., London.
 F. Strong Heaney, Esq., F.R.C.S., Liverpool.
 Dr. E. K. Lo Fleming, Wimborne, Dorset.
 Sir Richard Luce, K.C.M.G., C.B., Derby.
 Dr. Arnold Lyndon, O.B.E., Grayshott, Surrey.
 Dr. A. Mankucll, Bradford.
 A. W. Nuthall, Esq., F.R.C.S., Birmingham.
 Dr. D. A. Sheahan, Portsmouth.
 Dr. W. B. Crawford Treasure, Cardiff.
 Dr. E. O. Turner, Great Missenden, Bucks.

Scotland.

- Dr. G. W. Miller, D.S.O., Dundee.
 Dr. Hugh Miller, Hamilton.
 Dr. C. M. Pearson, Edinburgh.
Vacancy.

Ireland.

- Professor R. J. Johnstono, F.R.C.S., M.P., Belfast.
 Dr. Reginald C. Peacocke, O.B.E., Blackrock, co. Dublin.
 Dr. Denis Walshe, Graigue, Kilkenny.
Vacancy.

Seven Elected by Branches outside United Kingdom.

Dominions.

- Dr. Noel L. Clarke, London (Hong Kong and China, and Malaya Branches).
 T. P. Dunhill, Esq., C.M.G., M.D., B.S., London (S. Australian, Tasmanian, Victorian, and West Australian Branches).
Vacancy (Grouped Indian Branches).
 Dr. D. Ewart, O.B.E., Chichester (New Zealand Branch).
 Dr. T. Duncan Greenlees, St. Leonards-on-Sea (African Branches).
 Dr. W. F. Law, Dublin (West Indian and Canadian Branches).
 Sir Jenner Verrall, LL.D., Leatherhead (New South Wales and Queensland Branches).

Twelve Elected by Grouped Representatives.

England and Wales.

- Dr. T. Ridley Bailey, Bilston, Staffs.
 Dr. J. W. Bone, Luton.
 W. McAdam Eccles, Esq., M.S., F.R.C.S., London.
 Dr. C. E. S. Flemming, Bradford-on-Avon.
 Dr. A. Forbes, Sheffield.
 Dr. S. Morton Mackenzie, Dorking.
 Dr. F. Radcliffe, Oldham.
Vacancy.

Scotland.

- Dr. C. E. Douglas, Cupar, Fife.
Vacancy.

Ireland.

- Dr. J. S. Darling, Lurgan, co. Armagh.
 Dr. R. B. Mahon, Galway.

Eight Elected by Representative Body.

- Dr. H. Guy Dain, Birmingham.
 Dr. E. R. Fothergill, Hove.
 Dr. R. Laugdon-Down, Hampton Wick.
 Dr. E. Lewys-Lloyd, Towyn, Merioneth.
 Dr. J. A. Macdonald, LL.D., Taunton.
 H. S. Souttar, Esq., C.B.E., F.R.C.S., London.
 Dr. John Stevens, Edinburgh.
 E. B. Turner, Esq., F.R.C.S., London.

Service Representatives.

- Colonel T. D. Barry, C.B.E., R.A.F., London. (*Royal Air Force Medical Service*).
 Surgeon Rear Admiral Sir Percy Bassett-Smith, K.C.B., C.M.G., R.N.(ret.), London. (*Royal Naval Medical Service*).
 Colonel Sir W. J. Buehauan, K.C.I.E., I.M.S.(ret.), Dublin. (*Indian Medical Service*).
 Major-General Sir William Macpherson, K.C.M.G., C.B., A.M.S.(ret.), London. (*Royal Army Medical Corps*).

COMMITTEES.

EX OFFICIO MEMBERS OF ALL STANDING COMMITTEES.

The following are members *ex officio* of all Committees:

- Sir William Macewen, C.B., LL.D., M.D., F.R.C.S., F.R.S., D.Sc., Glasgow (*President*).
 Dr. R. Wallace Henry, Leicester (*Chairman of Representative Body*).
 Dr. R. A. Bolam, LL.D., Newcastle-upon-Tyne (*Chairman of Council*).
 Dr. G. E. Haslip, London (*Treasurer*).

FINANCE COMMITTEE.

The *ex-officio* members.

- The Chairmen of the following Committees: Organization, Journal, Science, Medico-Political and Parliamentary, Central Ethical, Insurance Acts; with—
 Dr. J. T. D'Ewart, Manchester.
 W. McAdam Eccles, Esq., M.S., London.
 N. Bishop Harman, Esq., F.R.C.S., London.
 A. Lucas, Esq., F.R.C.S., Birmingham.

ORGANIZATION COMMITTEE.

The *ex-officio* members.

- Dr. F. J. Baidon, Southport.
 Dr. H. S. Beadles, London.
 Russell.
 Dr. L.
 Dr. T.
 Dr. Arnold Lyndon, O.B.E., Grayshott, Surrey.
 Dr. S. Morton Mackenzie, Dorking.
 Sir Jenner Verrall, LL.D., Leatherhead.

JOURNAL COMMITTEE.

The *ex-officio* members.

- Dr. G. A. Allan, Glasgow, W.
 Dr. F. J. Baidon, Southport.
 Dr. R. C. Buist, Dundee.
 Dr. C. O.
 Dr. E. K.
 E. Lewis Lacey, Esq., F.R.C.S., Leicester.
 Dr. J. A. Macdonald, LL.D., Taunton.
 A. W. Nuthall, Esq., F.R.C.S., Birmingham.
 Chairman of the Central Ethical Committee.
 One Member to be appointed by the Organization Committee.

SCIENCE COMMITTEE.

The *ex-officio* members.

- The Rt. Hon. Sir T. Clifford Allbutt, K.C.B., LL.D., M.D., F.R.S.,
 Dr. H. J.
 Professor
 Professor
 Professor
 Professor
 London.
 Dr. H. J. M. Milbank-Smith, Worthing.
 Sir Humphry Rolleston, K.C.B., D.C.L., M.D., London.
 H. S. Souttar, Esq., C.B.E., F.R.C.S., London.
 E. B. Turner, Esq., F.R.C.S., London.

CENTRAL ETHICAL COMMITTEE.

The *ex officio* members.

- Dr. J. W. Bone, Luton, Beds.
 Dr. H. C. Bristowe, Wington, Somerset.
 Dr. C. Buttar, London.
 Dr. James Don, Newcastle-upon-Tyne.
 Dr. C. E. Douglas, Cupar, Fife.
 J. Furneaux Jordan, Esq., F.R.C.S., Birmingham.
 Dr. R. Laugdon-Down, Hampton Wick.
 Dr. A. Lyndon, O.B.E., Grayshott, Surrey.
 Dr. H. C. Maclellan, M.B.E., Wolverhampton.
 Dr. E. W. G. Masterman, London.
 Dr. James Neal, Medical Defence Union, London.
 Dr. John Stevens, Edinburgh.

MEDICO-POLITICAL AND PARLIAMENTARY COMMITTEE.

The *ex-officio* members.

Dr. T. Ridley Bailey, Bilston, Staffs.
Dr. H. S. Beadles, London.
Dr. J. W. Bone, Linton, Beds.
Dr. H. B. Brackenbury, London.
Dr. H. C. Bristowe, Wington, Somerset.
Dr. H. Guy Dain, Birmingham.
Dr. C. E. S. Flemming, Bradford-on-Avon.
Dr. H. C. Mautier, M.B.E., Wolverhampton.
Dr. John Stevens, Edinburgh.
Dr. W. B. Crawford Treasuro, Cardiff.
E. B. Turner, Esq., F.R.C.S., London.
Sir Jemier Verrall, LL.D., Leatherhead.
Chairman of the Public Health Committee.

PUBLIC HEALTH COMMITTEE.

The *ex-officio* members.

Dr. T. Ridley Bailey, Bilston, Staffs.
Dr. W. F. Dcarden, J.P., Old Trafford, Manchester.
Dr. T. W. H. Garstang, c/o B.M.A., London.
Dr. T. Eustace Hill, O.B.E., Darlington.
Dr. W. J. Howarth, C.B.E., London.
Dr. Herbert Jones, Lynwood, Hereford.
Dr. E. W. Lewis-Lloyd, Towyn, Merionethshire.
Dr. C. Sanders, London.
Dr. W. Johnson Smyth, Bournemouth West.
Dr. E. H. Snell, Coventry.
Dr. James Wheatley, Shrewsbury.
Dr. F. E. Wynne, Sheffield.

INSURANCE ACTS COMMITTEE.

The *ex-officio* members.

Dr. H. Guy Dain, Birmingham (*ex-officio*).

Five elected by Representative Body:

Dr. H. S. Beadles, London.
Dr. H. Guy Dain, Birmingham.
Dr. Herbert Jones, Hereford.
Dr. E. K. Le Fleming, Wimborne, Dorset.
Dr. R. W. Craig, Midlothian.

With nineteen Direct Representatives of Local Medical and Panel Committees; a Representative each of the Hospitals Committee, of the Medical Women's Federation, of the Society of Medical Officers of Health, and of the Poor Law Medical Officers' Association (to be appointed).

HOSPITALS COMMITTEE.

The *ex-officio* members.

Dr. C. Buttar, London.
Dr. Astley V. Clarke, Leicester.
Dr. J. D. Comrie, Edinburgh.
Dr. H. Guy Dain, Birmingham.
W. McAdam Eccles, Esq., M.S., F.R.C.S., London.
Dr. C. E. S. Flemming, Bradford-on-Avon.
Dr. E. R. Fothergill, Hove.
Sir James Galloway, K.B.E., C.B., M.D., London.
N. Bishop Harman, Esq., F.R.C.S., London.
Dr. E. W. G. Masterman, London.
Dr. F. Radcliffe, Oldham.
H. S. Souttar, Esq., C.B.E., F.R.C.S., London.

NAVAL AND MILITARY COMMITTEE.

The *ex-officio* members.

Captain F. W. Goodbody, R.A.M.C.T.F., London.
A. M. Gray, Esq., C.B.E., F.R.C.S., London.
F. J. Strong Heaney, Esq., F.R.C.S.I., Liverpool.
Major-General Sir Richard Luce, K.C.M.G., C.B., A.M.S. (ret.), Derby.
Colonel T. D. Barry, C.B.E., R.A.F., London.
Colonel Sir Walter J. Buchanan, K.C.I.E., I.M.S. (ret.), Dublin.
Major-General Sir William Macpherson, K.C.M.G., C.B., A.M.S. (ret.), London.
Surgeon Rear Admiral Sir Percy Bassett-Smith, K.C.B., C.M.G., R.N. (ret.), London.

DOMINIONS COMMITTEE.

The *ex-officio* members.

Dr. I. W. Johnson, Bury.
Dr. J. A. Macdonald, LL.D., Taunton.
Dr. W. Paterson, London.
Dr. R. A. Wilson, Guernsey.
Dr. Noel L. Clarke, London.
Dr. P. Dunhill, Esq., C.M.G., M.D., B.S., London.
Dr. David Ewart, O.B.E., Chichester.
Dr. T. Duncan Greenlees, St. Leonards-on-Sea.
Dr. W. F. Law, Dublin.
Sir Jenner Verrall, LL.D., Leatherhead.
Vacancy (Grouped Indian Branches).

SCOTTISH COMMITTEE.

The *ex-officio* members.

Scottish Members of Council.

Dr. C. E. Douglas, Cupar, Fife.
Dr. G. W. Miller, D.S.O., Dundee.
Dr. Hugh Miller, Hamilton.
Dr. C. M. Pearson, Edinburgh.
Two vacancies.

With Direct Representatives of Scottish Divisions and members co-opted by the Scottish Committee.

WELSH COMMITTEE.

The *ex-officio* members.

Dr. T. Ridley Bailey, Bilston, Staffs.
Dr. W. B. Crawford Treasuro, Cardiff.

Members to be elected by:

Cardiff Division.
South-West Wales Division.
South Carnarvon and Merioneth Division.
Swansea Division.
North Carnarvon and Anglesey Division.
North Glamorgan and Brecknock Division.
Monmouth Division.
Denbigh and Flint Division.

ARRANGEMENTS COMMITTEE.

This Committee will consist of the *ex-officio* members, six members to be appointed by Council, and six to be appointed by the Portsmouth Executive Committee.

PARLIAMENTARY ELECTIONS COMMITTEE.

The *ex-officio* members.

Dr. H. B. Brackenbury, London.
Dr. H. Guy Dain, Birmingham.
W. McAdam Eccles, Esq., M.S., F.R.C.S., London.
Captain W. E. Elliot, M.C., M.P., House of Commons.
Dr. A. C. Farquharson, M.P., London.
Sir Thomas Flitcroft, Bolton.
Dr. T. W. H. Garstang, c/o B.M.A., London.
Dr. J. Goff, Windlesham, Surrey.
W. J. Greer, Esq., F.R.C.S., Newport, Mon.
N. Bishop Harman, Esq., F.R.C.S., London.
Dr. E. K. Le Fleming, Wimborne, Dorset.
Dr. J. A. Macdonald, LL.D., Taunton.
E. B. Turner, Esq., F.R.C.S., London.
Sir Jenner Verrall, LL.D., Leatherhead.
One representative of Medical Women's Federation. With power to co-opt:
(a) Not more than four other members of the Association; and
(b) A medical representative from the Local Election Committee formed in any area in which an approved Medical Candidate is standing for election.

COMMITTEE re EXPANSION OF ARMY MEDICAL SERVICE IN CASE OF NATIONAL EMERGENCY.

The *ex-officio* members.

Colonel T. D. Barry, C.B.E., R.A.F., c/o Grindlay and Co., London.
Surgeon Rear Admiral Sir Percy Bassett-Smith, K.C.B., C.M.G., R.N. (ret.), London.
Colonel L. Blandford, C.B.E., Worcester.
Dr. C. Buttar, London.
Russell Coombe, Esq., F.R.C.S., Exeter.
Dr. T. W. H. Garstang, c/o B.M.A., London.
N. Bishop Harman, Esq., F.R.C.S., London.
F. Strong Heaney, Esq., F.R.C.S., Liverpool.
Major-General Sir Richard Luce, K.C.M.G., C.B., Derby.
Dr. J. A. Macdonald, LL.D., Taunton.
Major-General Sir William Macpherson, K.C.M.G., C.B., A.M.S. (ret.), London.
E. B. Turner, Esq., F.R.C.S., London.
Sir Jenner Verrall, LL.D., Leatherhead.
With power to co-opt a member representing the temporary R.A.M.C. officers.

JOINT COMMITTEE WITH THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The *ex-officio* members.

The Chairmen of the following Committees: Public Health, Medico-Political and Parliamentary, Insurance Acts, Organization.
Eight to be elected by the Society of Medical Officers of Health.

SPECIAL COMMITTEE re NOTIFICATION OF VENEREAL DISEASES.

The *ex-officio* members.

Dr. H. Guy Dain, Birmingham.
Dr. E. R. Fothergill, Hove.
Dr. T. W. H. Garstang, c/o B.M.A., London.
N. Bishop Harman, Esq., F.R.C.S., London.
Dr. R. Langdon-Down, Hampton Wick.
Dr. J. McGregor Robertson, Glasgow, W.
E. B. Turner, Esq., F.R.C.S., London.
Sir Jenner Verrall, LL.D., Leatherhead.

OFFICE COMMITTEE.

The Office Committee is constituted as follows:

Dr. R. A. Bolam, LL.D. (Newcastle-upon-Tyne), *Chairman of Council*.
Dr. R. Wallace Henry (Leicester), *Chairman of Representative Body*.
Dr. G. E. Haslip, London, *Treasurer*.
Sir Dawson Williams, M.D., C.B.E., LL.D., D.Litt., *Editor*.
Dr. Alfred Cox, *Medical Secretary*.
L. Ferris-Scott, Esq., F.C.A., *Financial Secretary and Business Manager*.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Surgeon Commanders G. D. G. Fergusson to the *Curlew* on commissioning; H. A. Kelland-Knight to the *Pembroke* for R.N. Hospital, Chatham; D. H. C. Given to the *Victory*, additional for R.N. Barracks for duty with Surgeon Rear Admiral, Haslar, as Naval Health Officer, Portsmouth Command; C. H. Dawe to the *Fido*, additional for R.N. Barracks, Devonport, for duty with Surgeon Rear Admiral, Plymouth, as Naval Health Officer, Devonport; J. D. S. Millin to the *Glorious*; A. Woolcombe to the *Pembroke*, additional for R.N. Barracks, Devonport, for duty with Surgeon Rear Admiral, as Naval Health Officer. Lieutenant Commanders H. E. J. President, additional for three months' hospital course; M. S. Moore to the *Columbine*, additional for 12 N. Hospital, South Queensferry. Surgeon Lieutenant G. G. Mitchell to the *Clematis*. MANCHESTER CITY COUNCIL.—Third Assistant Medical Officer at the Monsall Fever Hospital. Salary, £250 per annum.

MANCHESTER ROYAL INFIRMARY.—(1) Assistant Director of the Clinical Laboratory. (2) Resident Medical Officer at the Barnes Convalescent Hospital. Salary, £350 and £300 per annum respectively.

MANCHESTER: ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Resident Obstetric Surgeon. Salary, £250 per annum.

MANCHESTER: VICTORIA MEMORIAL JEWISH HOSPITAL, Cheetham.—Resident Medical Officer. Salary at the rate of £150 per annum.

MINISTRY OF PENSIONS.—Junior Medical Officer at the Ministry of Pensions Hospital, Cannock Chase. Salary, £350 per annum.

NEWCASTLE-UPON-TYNE: UNIVERSITY OF DUREHAM COLLEGE OF MEDICINE.—Senior Demonstrator of Anatomy. Salary, from £500 to £700 per annum.

NORWICH: NORFOLK AND NORWICH HOSPITAL.—House-Surgeon. Salary, £150 per annum.

NOTTINGHAM GENERAL DISPENSARY.—Resident Surgeon (Branch). Salary, £300 per annum.

OPPORTHO: BRITISH HOSPITAL.—Medical Officer. Minimum income of £500 per annum guaranteed.

PORTRATHICK PARISH COUNCIL.—Medical Officer. Salary, £110 first year, rising to £120 second year.

PUBLIC DISPENSARY, 122, Drury Lane, W.C.—Resident Medical Officer. Salary, £105 per annum.

POTTS HOSPITAL, S.W.—Resident Medical Officer. Salary, £150 per annum.

QUEEN MARY'S HOSPITAL FOR THE EAST END, Stratford, E.—House-Surgeon. Salary, £150 per annum.

ROTHESMAN HOSPITAL.—Junior House-Surgeon (male). Salary, £150 per annum.

ST. MARY'S HOSPITAL, Paddington, W.—Medical Superintendent. Salary, £350 per annum.

ST. PETER'S HOSPITAL FOR STENT, Etc., Henrietta Street, W.C.—House-Surgeon. Salary, £75 per annum.

SEAFORD HOSPITAL SOCIETY, Greenwich, S.E.—House-Physician at the "Dreadnought" Hospital. Salary, £150 per annum.

THROAT HOSPITAL, Golden Square, W.1.—Resident House-Surgeon. Salary at the rate of £100 per annum.

W. TEE FOR TUBERCULOSIS.—VII Memorial Sanatorium.

WEST BROMWICH COUNTY BOROUGH.—(1) First Assistant Medical Officer of Health and Clinical Tuberculosis Officer. (2) Second Assistant Medical Officer. (3) Welfare Medical Officer. £700 and £500 per annum.

WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck Street, W.1.—Honorary Clinical Assistants.

WEST LONDON HOSPITAL, Hammoirsmith Road, W.—(1) House-Physician. (2) Two House-Surgeons (males). Salary, £100 per annum each.

WINSLEY SANATORIUM, near Bath.—Assistant Resident Medical Officer (male). Salary, £250 per annum, rising to £300.

CERTIFYING FACTORY SURGEONS.—The following vacant appointments are announced: Longtown (Cumberland).

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

BROSTEN, L. R., O.B.E., M.A., D.M., M.Ch.Oxon, F.R.C.S. Eng., Assistant Surgeon to the Queen's Hospital for Children, Hackney Road.

CAMERON, S. J., M.B., Ch.B.Glas., F.R.F.P.S., Gynaecologist, Western Infirmary, Glasgow.

GRONMAN, S., M.R.C.S., L.R.C.P., Junior Assistant Medical Officer, Cardiff Mental Hospital, Whitechurch.

LOCKE, R. W., M.B., B.S.Durh., Resident Medical Officer, Newcastle Dispensary, vice I. M. Pirie, M.C., M.B., B.S.Durh.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which must be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

MARRIAGES.

HARPER—MAINWARING.—On August 14th, Francis Strachey Harper, M.B., C.M., of Broughton, Bucks, to Una Evelyn, eldest daughter of the late Captain Percy Mainwaring and Mrs. Mainwaring of Shoreham, Sussex.

TOITE—WILSON.—At Dublin, on the 7th of August, Captain Mark Tuile, M.C., Connaught Rangers, I.P. co. of Longford, of Killeen, and Clonoe, co. Cavan, eldest son of the late Major Robert Stratford Tuile, R.I.R., to Ethel, sixth daughter of the late Dr. Thomas Wilson and Mrs. Wilson, of Edgeworthstown.

DEATH.

THOMAS.—On the 7th inst., at his residence, 200, Bristol Road, Birmingham, William Thomas, M.B.Lond., F.R.C.S., aged 82.

British Medical Journal.

SATURDAY, AUGUST 19TH, 1922.

THE DISCUSSION ON BACTERIOLYSIS.

THE widespread interest which has been manifested in the subject of the breaking down of bacteria by lytic agents has been largely due to the fact that Dr. d'Herelle, of the Pasteur Institute, Paris, startled the bacteriological world with the hypothesis that this bacteriolysis is due to the agency of a living ultramicroscopic parasite of bacteria. That creatures so lowly as single and apparently undifferentiated bacterial cells should be preyed upon by organisms even lowlier than themselves and become the victims of parasites of inconceivably small dimensions was a conception that at once arrested attention. It was boldly put forward by Dr. d'Herelle in a paper published in September, 1917; in it he affirmed the existence of an invisible microbe which antagonized the dysenteric bacillus. His affirmation has since been the subject of numerous researches and, incidentally, much controversy. Briefly stated, the facts are that it is possible to extract from many forms of organic material an active substance which will pass through the pores of the finest filter, and possesses the property of inducing lysis in a bacterial culture. This active substance, which d'Herelle maintains to be a living organism, can be shown to multiply when in contact with living bacteria, and can be carried over from tube to tube, producing lysis in successive cultures. This is sometimes known as the "phenomenon of d'Herelle," but a similar process of bacteriolysis was described by Twort in 1915, and it was the almost unanimous opinion of those who took part in the discussion in the Section of Microbiology of the annual meeting of the British Medical Association at Glasgow that the Twort and d'Herelle phenomena are identical. Anyone who is at the pains to read the discussion, as reported in this issue (and a very fascinating story it is), will be disposed to accept the statement, and to agree that though d'Herelle cannot be given priority in the discovery of the phenomenon, he undoubtedly deserves credit for having awakened a lively interest in the question raised, and for having stimulated others by his imaginative reasoning to a closer examination of a subject of great scientific interest which may prove to be of great practical importance to medicine.

Concerning the broad facts, all who have worked at the subject are in complete agreement. A broth culture of such an organism as *B. dysenteriae* can undoubtedly be dissolved by the addition of a few drops of a sterile fluid obtained by filtering a faecal suspension through a Berkefeld or Chamberland filter. This is in itself a remarkable fact; but its unexpectedness is entirely eclipsed by the discovery that a drop of the lysed culture can induce exactly the same change in a second culture, and a drop from this in a third, and so on in series. The active substance must certainly have multiplied and regenerated itself at the expense of the bacteria. For d'Herelle the only possible explanation is that there passed through the pores of the filter an ultramicroscopic parasite which, added to a bacterial culture, attacks the organisms, dissolves them by its ferments, and so multiplies and regenerates itself. This organism he has named the "bacteriophage," and he claims that, on the one hand, its virulence can be increased by passage, and, on the other, that the bacteria themselves can be educated to develop protective substances

and so defend themselves from the assaults of their enemy.

It must be conceded at once that we have little or no knowledge of forms of life smaller than can be observed with the highest magnifications of the microscope, of microbes more minute, for instance, than the *Micrococcus melitensis*. Yet the imposing list of filter-passing organisms justifies the belief that living things of smaller dimensions exist and may cause most serious disease when they attack man. We must assume that living organisms have been evolved from simpler forms, and no one imagines that this evolution began with a coccus. In the scale of evolution bacteria represent comparatively complicated structures, built up of innumerable living particles; doubtless more primitive forms have existed and probably exist to-day. The theory of d'Herelle cannot be dismissed because it presumes the existence of living agents of inconceivably small dimensions. But we have to ask ourselves if the faculty for regeneration, which is the main foundation on which the bacteriophage theory is based, is an attribute only of living organisms. Dr. André Gratia suggested two analogies for reproduction apart from living beings. "Fire," he said, "is not living, and yet fire is endowed with the power of reproduction. When once lighted, thanks to an initial impulse, such as an electric spark or the mere striking of a match, it can be indefinitely reproduced if fuel is provided." His analogy of the transmissible coagulation of blood in series is also worthy of consideration. The arguments for and against the existence of an ultramicroscopic parasite are set out in the discussion on the papers of d'Herelle and Twort; it is sufficient to remark in passing that the majority of those who have studied the phenomenon are not convinced that d'Herelle's premisses are fully established; they are still looking for a cause "which does not tax too severely one's sense of the naturalness or the likelihood of things."

Dr. Twort, when he first observed the appearance of bacteriolysis in culture, attributed it to an acute infective disease of micrococci, but "though the possibility of its being an ultramicroscopic virus has not been definitely disproved," he now declares that "on the whole it seems probable, but by no means certain, that the active transparent material is produced by the micrococcus." If so, we should expect that the bacteria would benefit by this rapid disintegration of some members of the colony, and Dr. Twort has observed certain long forms of *Bacillus coli* found associated with the lytic agent in the upper part of the intestinal tract which could be cultivated only after the lytic agent had been eliminated. These "special forms" were found to be more numerous in young cultures, and after six to twelve hours were partially dissolved. He suggests that the lytic agent is a normal product of the bacterial cell, formed for the purpose of causing lysis of the "special forms" and so setting free toxins or substances antagonistic to other bacteria. Such a theory presupposes the early differentiation of a bacterial colony into groups with special functions, some destined by a process of sacrificial autolysis to liberate poisonous substances and thus protect their more resistant relatives.

The discussion at Glasgow has undoubtedly done much to clear the air, and this free and open exchange of views of experts will be welcomed by workers at this subject in all parts of the world. Bacteriolysis may well prove to be of great practical importance to medicine, for whatever be the cause of this remarkable phenomenon it is obvious that when the problem is solved it may throw a flood of light on resistance to disease and open up new avenues of treatment. So far, however, the results of using the bacteriophagic element in combating infection have not been very convincing, and it cannot be expected that much practical advantage

will be obtained until we have a more precise knowledge of the factors involved. It is too soon to elaborate any comprehensive theory, for new manifestations of similar phenomena, such as the lysozyme reaction of Fleming, are being reported, and it will be necessary first to study the simplest examples of bacteriolysis by accurate quantitative methods. The problem is not limited to the domains of medical bacteriology, but has awakened the interest of students of all branches of biology, and the results of further researches will be watched with keen interest.

THE VITAMIN CONTENT OF VEGETABLE OILS AND FATS.

VEGETABLE oils and fats are assuming an increasing importance in nutrition, for fats are indispensable in a complete diet and animal fats are dear; hence the world is being ransacked for sources of vegetable fats and oils. Vegetable fats contain, however, very little vitamin A, and hence the replacement of animal fats by vegetable fats in human food raises important questions as to the adequacy of the supply of vitamin A in the diet. In a normal mixed diet vitamin A is contained chiefly in green vegetables and animal fats. Unfortunately the poorer urban populations often do not eat green vegetables with regularity and in sufficient quantity, and there is the tendency among them to substitute cheap vegetable fats for the more expensive animal fats; they tend, therefore, to live on a diet very poor in vitamin A.

Deficiency of this vitamin has not been shown to produce any well-defined disease, in the way that deficiency of vitamins B and C respectively produces beri-beri or scurvy; hence the serious effects due to deficiency of vitamin A are apt not to be fully recognized. It is known, however, that the deficiency produces increased susceptibility to infections, and is also one of the chief causes favouring the appearance of rickets. Partial deficiency of this vitamin may also produce sterility. Animals can store vitamin A in their fat and can draw upon this supply, and hence marked symptoms of vitamin A lack do not readily appear in a healthy adult animal. The animal in order to produce the store of vitamin A must, however, have obtained it at some period or another, and all the evidence available points to the fact that it is impossible to rear successive generations of healthy animals if they are fed on a diet seriously deficient in vitamin A.

These facts suggest that the experiment which is proceeding at present of feeding about half the population of this country on a diet deficient in vitamin A is likely to produce serious consequences. The vitamin content of vegetable fats and oils is on this account a matter of great practical importance, and Drummond and Zilva¹ have recently carried out an interesting research on the subject. They first investigated the vitamin content of the oil-bearing seeds; they found that linseed contained a fair amount of vitamin A, but that in seventeen other varieties of seeds examined there were at most only traces of this vitamin. Though most of the vitamin A present in the seeds passed into the crude oil, the quantity might be less than one-tenth the vitamin A content of butter. The only exception was crude palm oil; highly pigmented specimens of this oil in some cases had a vitamin A content equal to that of butter; unfortunately it was found impossible to render the crude palm oil palatable by any process which did not involve destruction of the vitamin. The result of these researches thus leads to the general conclusion that the amount of vitamin A in vegetable oils

is low because there is very little of this vitamin in the seeds from which the oil is produced. No vegetable oil has been found which is at once edible and rich in vitamin, but the high vitamin content of crude palm oil shows that there is a possibility of such an oil existing. An oil of this kind would be of the greatest value, for it would afford a cheap source of supply of vitamin A in the manufacture of margarine.

The results of this research are to a certain extent disappointing, for it had been hoped that the absence of vitamin A from vegetable oils was due to destruction in manufacture; if this had proved to be true it would probably have been fairly easy to remedy the defect. Since the deficiency, however, appears to be due to the fact that the vitamin is absent from the raw material used, or present only in very small quantity, the only hope of achieving the object in view is to find some other oil resembling crude palm oil in its vitamin content but not in its taste.

THE GROWING ABUSE OF COCAINE.

Nor only do the columns of the daily press provide indubitable evidence of the growing abuse of cocaine, but a communication made last month to the Paris Académie de Médecine by MM. Courtois-Suffit and René Giroux serves to confirm the alarming increase in the illicit traffic of the "*poudre folle*," or "*respirette*," as it is colloquially called. In Paris alone the arrests of those caught pursuing this remunerative and degrading commerce have increased from 42 in 1917 to 212 last year. The bulk of the alkaloid is said to be imported from Germany, and among the troops occupying the Rhineland and employees on the European expresses there are alleged to be those who act as intermediaries. Many and ingenious are the tricks resorted to by cocaine hawkers in the Quartier Latin and the cafés of Montmartre. The trade is also said to flourish in Marseilles and Toulon, in Nice, Monte Carlo, and Biarritz, as well as in Alsace-Lorraine. The wholesale price of cocaine is about 1,300 francs a kilogram, and as it is retailed at 20 to 30 francs a gram it yields a rich profit to the agents in this clandestine business. The authors of the communication cited assert that in America cocaine vendors invade the universities and colleges and insidiously offer the students gratuitous samples of the alkaloid, feeling assured that its victims will resort to them again and again as they become addicted to it, and thus a regular custom is secured. In France, as in this country, severer penalties are called for to check this toxic peril. In a previous communication to the Académie, noticed in our columns on September 10th, 1921 (p. 414), Dr. Courtois-Suffit stated that under the present law in France the highest fine that can be imposed is 10,000 francs. He related an instance in which it had been possible to make 130,000 francs on a single transaction, so that even the maximum fine would have little effect; in practice the fines imposed are very much smaller, and the French courts very seldom exercise the power they have to sentence the offender to a term of imprisonment as well as a fine.

It is clear that, as the authors of the International Opium Convention of 1912 held, the traffic in dangerous drugs of addiction needs international co-operation and control from the source, in order to limit the use of opium, morphine, cocaine, their derivatives and allies, to medical and legitimate purposes only.

The members of the Council of the League of Nations have now before them the second report of their Advisory Commission and the answers to the set of questions they issued; these will also doubtless be considered by the forthcoming meeting of the Assembly. Some fifteen nations among the fifty-one members of the

¹ J. C. Drummond and S. S. Zilva, Studies of the Nutritive Value of the Edible Oils and Fats, *Journ. of the Soc. of Chem. Industry*, xli, 125r, 1922.

League have not as yet brought the Convention, even partially, into operation. The amounts of these drugs required for legitimate purposes in each country or in the world at large remain undetermined, and very few statistics have as yet been furnished to the League giving details of the actual manufacture, import, export, and consumption of these drugs even in European countries. It is, however, known that enormous quantities of morphine and cocaine, largely of European and American origin, have been reaching China and Japan during the last few years, and China has again become, like Turkey, Persia, and India, a large producer of opium, despite the benevolent intentions of its feeble central government. Some of the figures vouchsafed in reply to the questions asked by the League of Nations are disquieting, and seem to show that the production of morphine and cocaine is out of all proportion to any probable legitimate requirement. Thus Great Britain manufactured 18,000 kg. of morphine in 1920, half of which was exported. While it is stated on one page that only half a kilogram was exported from Great Britain to Japan in 1920, on another page it appears that in the same year Japan imported 22,000 kg., of which 5,000 came from England and 9,000 from the United States. Again, in 1920 Japan, besides manufacturing 4,100 kg. of cocaine, imported 3,500 kg. of the same drug, about half of which came from the United States. The statistics from the United States had not been received at the time when the Advisory Commission compiled its replies to the questions. Attention is, however, drawn to the "serious discrepancies between the export of drugs from Great Britain to Japan as shown in the British returns, and the imports to Japan from Great Britain as shown in the Japanese returns," and the significant remark is made that "no light has been thrown on the methods by which such large quantities of drugs were apparently exported from Great Britain without the knowledge of the Customs authorities, and the matter calls for further investigation." A new law is said to have been enacted in Japan to take effect on January 1st, 1921, and it is hoped that it "will do away with the abuses indicated." A detailed study of the replies to the questions from which we have culled these extracts would serve to show the extent of the world-wide abuse of drugs of addiction which is going on, as well as the need for impartial international vigilance and effective international co-operation and control.

THE BACTERIOLOGY OF INFLUENZA.

WHEN fifty years hence the progress of bacteriological discovery in the early years of the twentieth century comes to be reviewed the historian will probably call attention to the fact that whilst British investigators made many remarkable discoveries concerning the origin of diseases not met with in this country, they achieved little for the elucidation of the nature of the two commonest scourges of their native land—namely, the common cold and influenza. Such criticism would not be unjustified, for though we speak with confidence to-day of the causal agent of such diseases as malaria, sleeping sickness, and plague, great uncertainty can be detected in our discussions of nasal and bronchial catarrh. The explanation is not to be found in an altruistic commiseration of the sufferings of others accompanied by a neglect of our own. It is due to the fact that we are at present very ill-equipped for the study of those minute forms of life, organisms less than 0.5 micron in diameter, which will pass through the pores of a porcelain filter and yet cannot be satisfactorily stained or cultivated on solid media. An increasing volume of evidence has accumulated indicating that the common cold is caused by one of these ultramicroscopic viruses, and that the bacteria which are found in the secretions of nasal catarrh are no more than secondary

invaders. From the paper on influenza with which Dr. Gordon opened the discussion on the bacteriology of influenza in the Section of Bacteriology of the Annual Meeting at Glasgow, reported in this issue, it will be seen that he has isolated a filter-passing organism from an epidemic of the disease, and has thereby confirmed and extended the experimental work of others, notably in America and Japan. Down to the time of the great epidemic which swept over the whole world in 1918 the assertion that Pfeiffer's bacillus was the causal organism had been very generally accepted. The many bacteriologists who turned to the study of influenza in this and subsequent outbreaks began with a bias in favour of Pfeiffer's bacillus, but two difficulties at once arose: one was that the organism was often not found in typical attacks of influenza, and the other that it appeared to be widely distributed, being found in normal throats, and in patients suffering from measles and pneumonia. It must be admitted that as knowledge of the requirements of Pfeiffer's bacillus has increased it has been recovered much more frequently, both from the catarrhal secretions and from *post-mortem* lesions; this is amply proved by Professor McIntosh's work for the Medical Research Council (BRITISH MEDICAL JOURNAL, July 22nd, p. 137), of which he gave a summary to the Section. Experimental inoculation into animals although yielding instructive results has not proved a final court of appeal, because, with the exception of the leucopenic blood response, these animals do not react to influenza quite in the same way as man. It may be said at once that all who have worked at this subject are agreed that influenza-like lesions can be produced in the respiratory tract and lungs by the injection of Pfeiffer's bacillus or even with filtered cultures of it. The point in dispute is, What initiates the attack? Is there not some other factor apart from the influenza bacillus, some agent which prepares the way, leaving damaged epithelium on which the influenza bacillus can act? No organism can continue to exist in the respiratory tract unless living in intimate biological relation with the respiratory mucous membrane and secretion, and it is possible that the influenza bacillus requires the co-operation of some other virus to enable it to act as a parasite to man. In this connexion the work of Dr. Twort is suggestive, for he has shown that Pfeiffer's bacillus will grow readily on media containing no blood when living in symbiosis with a minute filter-passing organism. The difficulties which beset the study of filter-passing micro-organisms are many. These living forms cannot be clearly seen—on culture the only indication of their growth is an appearance of "cloudiness" in a fluid medium; the only definite proof of their existence is that on inoculation they produce a disease which can be transmitted in series. There must be different species of ultra-microscopic viruses, for on inoculation they cause widely different symptoms; the only method of labelling a virus, however, is by the disease it produces. Moreover, as Levaditi has demonstrated, similar ultra-microscopic viruses may be found in normal buccal secretions. The only method of isolating these organisms is by passage through a filter, and filtration is obviously a very crude procedure, for no two filters can be proved to be wholly alike in the size of their pores. Clearly, in the face of so many technical difficulties, all claims made for the discovery of any ultra-microscopic infective agents must be accepted with caution, but the facts Dr. Gordon records are of great importance. He has grown an ultra-microscopic parasite from the filtered secretion of patients suffering from influenza; he has been able to detect these minute particles in fresh influenzal secretion; and he has succeeded in staining the virus recovered in his cultures. Though, as he says, the methods of staining these "parasites" leave much to be desired, yet something has been definitely accomplished along these lines. He does not claim that this ultra-microscopic virus is certainly the cause of influenza, but he has proved that it is present, and that, when once the necessary technical skill has been acquired, it can be recovered constantly from influenza and common colds. The study of these infinitely minute forms of life is still in its infancy, but now that attention has been directed to their importance we may feel confident that the

technical difficulties will be overcome. As for the common cold there will probably be plenty of opportunity for research in the coming winter, and investigators are not likely to be handicapped by an insufficiency of "suitable cases."

PHYSICAL EDUCATION OF GIRLS.

We publish elsewhere (p. 321) an account of the report on the effects of physical education on girls, prepared by a Joint Committee instituted on the initiative of the College of Preceptors. It is a really valuable contribution to a subject about which a great deal has been written, much of it of little or no value. Of the facts brought out in the evidence given by medical practitioners to the Joint Committee and analysed in the report of the Medical Committee, which is published in full, one of the most important was that, notwithstanding the very large number of girls who have played games and gone in for athletic exercises during the last twenty years, the number of instances in which there was definite evidence of any physical injury was extremely small. Even the number of cases of "accidents of the game," such as a hockey or cricket ball in the wrong place, were practically negligible. We are indebted to Mr. E. B. Turner, one of the Representatives of the British Medical Association on the Joint Committee, for the following observations. "It will be noticed," he writes, "that the committee has expressed no opinion on the advisability of boys and girls over the age of 14 playing together in mixed hockey matches and other competitive games. It seems that such games seriously undertaken will not be good either for the girl or the game, as if the game is slowed down to the capacity of the girl it suffers, and if the girl, with the large amount of pluck so many of them have, attempts to adapt her speed and capacity to that of the stronger boy, it is possible that she may be injured. Of course, this does not apply to country-house friendly games, but to serious matches. In regard to competitive athletic sports, if girls prepare themselves properly and are efficiently taught, no harm is likely to result, provided the distance and other conditions of the contests are properly adapted to them. Tug-of-war, however, is by no means advisable, and should be prohibited. Some of those who answered the questions with regard to rowing drew a distinction between 'rowing' and 'sculling,' considering sculling by far the better of the two. From an intimate personal knowledge of what was probably one of the best double-sculling crews that ever represented a woman's college or university, I can say that nothing but good resulted from the racing competitions, but in this instance members of the crew took care to get and keep very fit. It must be understood with regard to the whole of this question that the physical conformation and structure of the young girl will not allow her to 'put up' such good performances as a boy; but there is not the slightest objection to girls taking part in practically all the same games as boys provided they take care to commence gradually and to continue keeping in condition. A man or a boy may do himself irremediable mischief by taking part in a strenuous game or athletic competition when untrained, and the same obtains with regard to the woman or girl; probably the greater number of the cases of injury reported were dependent on this cause. The reference in the report to the necessity of properly fitting a bicycle to the rider is most useful. Many girls for aesthetic reasons ride with the reach two or three inches too long for them, and this may cause mischief as well as interfere with the really effective control of the machine. It appears possible that excessive riding astride on horseback, especially in early youth, may prejudicially affect the muscles and bones of the outlet of the pelvis. The experience of one medical woman, based on her work with over 1,500 girls, was that when about 35 per cent. of the whole number of the girls took part in games, or went in for any hard exercise during the menstrual period, about 67 per cent. of the whole suffered from disturbances, functional and otherwise; but when 97 per cent. played games and took exercise during that time, only about 30 per cent. suffered any disturbance of the function. This is a matter of very great importance,

more especially in its bearing on the treatment of dysmenorrhoea by exercise; considerably more investigation is required. The opinion of almost everyone who gave evidence was that 'team games' had a most beneficial effect upon the character and disposition of all the girls who took part in them; the spirit of sportsmanship thus inculcated was of untold worth. There is no doubt that the custom of the universities should be observed and that before commencing an athletic career at school girls should be examined and passed as fit by a medical practitioner who thoroughly understands the subject. My own experience convinces me that one result of the athletic movement among girls during the last thirty years has been a most noticeable increase in height and other physical developments. In many cases, as obtains among boys, girls who have been first-class at their work and taken high honours, have also been very prominent athletes in their schools and colleges."

MILD SMALL-POX.

THE Ministry of Health has issued a useful leaflet on outbreaks of small-pox of mild clinical type. It states that a few such outbreaks have occurred in England during the present year; that there have been no fatal cases; that constitutional symptoms have been slight even when the rash has been abundant; and that the mildness of type is not limited to the vaccinated nor to patients of any particular age, but is related to the character of the small-pox infection itself. Such cases are sometimes being reported as "varioid" or "alastrim." Investigations have been made by local health officers and hospital physicians, by members of the Ministry's medical staff, and by other experts with special experience of small-pox. It is evident, the leaflet says, from their reports that the disease is really small-pox, and that the outbreaks are to be classed with the epidemics of mild clinical type which have occurred from time to time both at home and abroad. The incubation period has usually been that of variola, whilst the distribution of the rash distinguishes it from varicella. In a few instances there is some evidence that there has been an unusually long interval between the initial symptoms and the appearance of the rash; in some the rash has seemed to come out in successive crops. As regards the action which should be taken when an outbreak occurs it is stated emphatically that none of the customary and necessary preventive proceedings, including vaccination, should be omitted; that close inquiry should be made as to any concurrent prevalence of chicken-pox, so as to secure differentiation, and that to that end chicken-pox should be made temporarily notifiable wherever necessary; for administrative purposes all cases to which the terms "varioid" or "alastrim" are applied should be looked on as small-pox. Attention is called to the fact that both in the international list of causes of death, and in the *Nomenclature of Diseases* of the Royal College of Physicians, "varioid" is included under the generic term "small-pox," and so also in the weekly official returns of notified diseases, the two special terms when used being indicated in a footnote. A good deal of correspondence regarding "alastrim" and "amaas" has been published in the JOURNAL. The latter term comes from South Africa, and is equivalent to milk-pox. The derivation of the former is not so clear, but mild small-pox in Brazil was written of as *alastrim* a number of years ago. The first syllable of the word is perhaps the Arabic definite article, as in alcohol and alchemy. It is confusing to introduce such terms needlessly into the medical vocabulary. Where the disease is recognized in this country, however benignant in strain, the established term should be applied to it, with such words as "mild" or "modified" added in explanation. Last week we published a letter from Dr. R. U. Moffat showing that small-pox came to be called "Kaffir pox" in Kimberley forty years ago, because the place depended for food and fuel on bullock-wagon transport, and was threatened with starvation owing to the alarm of small-pox stopping the traffic. Then the authorities gave currency to the statement that the disease was only Kaffir pox, in order to allay fear. In his Milroy lectures in 1919, Dr. J. C. McVail discussed the

varieties of small-pox, and showed that mild types had existed and bred true in the eighteenth century, and that Jenner, before he introduced cow-pox, had suggested that material from one such outbreak should be used for variolation instead of the much more severe strains normally prevalent. In recent times mild small-pox has prevailed in many parts of the world—South America, the United States, Canada, Australia, and the midlands of England.

MEDICAL RESEARCH AND NATIONAL LIFE.

SIR WALTER FLETCHER's address at the annual meeting of the Research Defence Society has been published in the July number of the Society's journal, *The Fight against Disease*. He is able, as Secretary of the Medical Research Council, to speak with authority. He did well to praise "the beauty and interest of the work that is being done, the extraordinary skill and patience of the men who are doing it, the enormous services it is rendering to the country, and the great boon it brings us in lightening as it does the burdens of pain and disease." For want of time, he took only two instances—the study of the accessory factors of food, and the study and standardization of pituitary extract—two only, out of the host of instances of research pursued for the good of the country. But the whole address gives us a notable picture of a man who understands and admires and zealously helps the scientific work which is being done, as a State service, for the health and efficiency of the nation. It is strange, for us who know the facts, to think of the opposition and the hatred which have lately been set going against the Medical Research Council. This ill-will is one of the chief products of the antivivisection societies. The work for the health and efficiency of the nation involves experiments on animals. Therefore it is attacked by the usual antivivisection methods. A few weeks ago 102 members of the House of Commons voted for Lieutenant Commander Kenworthy's ridiculous bill "to prevent the application of public money to vivisection experiments." When we reckon how much public money is applied in payment of these 102 members we are the more sorry at the misuse of their votes. Happily, 170 members voted the right way. So the bill, drafted by the leader of one of the antivivisection societies, and sprung on the House, was properly defeated. It will doubtless turn up again. For our masters are in need of more education in these matters. Antvivisection is not content with mere opposition to experiments on animals. It goes on to assert that discoveries thus made are fallacious and valueless. By this impudent assertion it pleases its dupes. As the report of the Research Defence Society says, "The wild campaign, on which one of the antivivisection societies spent £2,000, to hinder the protection of the army against typhoid brought antivivisection into disgrace and contempt, from which it has not yet recovered. But our opponents have plenty of money, and they spend some of it in the propagation of slander and falsehood. Especially, they are trying to follow the advice of one of their leaders, 'Our hope is not in the idle rich; we must touch the heart of the people.' They seem to think that 'the people' will swallow any amount of nonsense, and they seek to persuade ill-educated hearers and readers that diphtheria antitoxin, and antiseptics, and the protective treatment against tetanus are wrong and absurd. Thus, the antivivisectionists are out, not only against experiments on animals, but against methods of practice which are used and approved in every country of the world. Our Society has to reckon with this false propaganda; we have to deal with antivivisection as an enemy of the people." This, indeed, is what antivivisection has become. Bad enough to pour out floods of abuse and slander. Bad enough to try to hinder physiology and pathology. Far worse to put a stack of tracts in the waiting-room of a railway station, advising the public to have nothing to do with diphtheria antitoxin. An immense amount of money is being spent on this evil sort of work. A little handful of experienced perverters of the truth has enlisted many credulous folk who do not realize that they have entered the service of the enemy

of the people. It is all very well to call them cranks; but our immediate business is to undo the harm which they are doing.

THE CAUSATION OF SEX.

Those interested in the causation of sex will be glad to have their attention drawn to an investigation of the alternation of sex in the oyster which Dr. J. H. Orton is making at the Plymouth Marine Biological Laboratory. He has also made some curious observations on sex change in the American slipper-limpet (*Crepidula fornicata*). That alternation of sex does occur in these creatures seems to be established beyond doubt. The novelty of Dr. Orton's recent contribution to *Nature* (vol. 110, p. 212) lies in the evidence he advances of the rapidity with which the change may occur. He has made a large number of observations, and, though some are still incomplete, he is able to report several suggestive facts. In June, 1921, a sexually mature male oyster, not more than twenty-three weeks old, was collected from the river Blackwater. A number of its fellows of the same age were obtained on specially prepared shells and kept isolated in the sea until July, 1922. A large one among them, about an inch in diameter, was on July 3rd found carrying thousands of young oyster embryos. Dr. Orton assumes that this individual oyster, like its fellows, became sexually mature as a male, and spawned as a male in June, 1921. In July, 1922, as has been said, it had spawned as a female; but a fortnight later (July 18th) it "was again sexually mature and practically ready to spawn as a male. Thus this oyster has already had two and probably three experiences of sex alternating from male (?) to female and from female back to male within about one year." Dr. Orton is not yet in a position to explain why these sex changes occur in the oyster, but is indisposed to attribute them to changes in the environment; he thinks that "the factor for sex causation is within the control of the organism." In this opinion he is confirmed by a study of the slipper-limpet. The young male of this species which has settled on another slipper-limpet has, Dr. Orton says, a "beautifully shaped and well-developed healthy black penis." If the other limpet is a female the limpet settled on it remains male and fructuous as such for a variable time, which may be as long as five or six years or as short as one. If the male has settled on the left side of the female—the wrong side for copulation—it nevertheless retains its maleness and even develops "an unusually fat and extensible penis capable of stretching probably twice as far as usual." If, on the other hand, the young male falls on some indifferent object the penis is "reduced to a mere discoloured trace," and the individual becomes female. Dr. Orton therefore comes to the conclusion that "the males on the females knew that the latter were there and tried their best to reach them, whilst the totally isolated ones have resigned themselves unreservedly to a complete sex change." It is a far cry from the oyster and the limpet to man, but the failure under these very simple conditions to establish any influence of the environment is certainly significant.

THE COST OF GERMAN PERIODICALS, BOOKS, AND TREATMENT.

The anomalous condition of the European exchanges, which is threatening to upset some of the time-honoured teachings of political economy, is being exploited with not a little success by German publishers. The *Zeitschrift für Biologie* is a case in point. This useful periodical has approximately as many subscribers outside as inside Germany, and the honour in which it is held in Germany is shown by the fact that its publishers were recently voted a subsidy of 30,000 marks by the scientific committee appointed some time ago to watch over the interests of the most important German scientific publications, the existence of which was threatened by Germany's financial embarrassments. The publisher of this periodical has recently announced that, in spite of its limited circulation and the cost of printing, he is able to dispense with any subsidy and is in the position to double the

payments to contributors. He attributes this to the policy of charging foreign subscribers at the pre-war rate in the currencies of their own countries. Had he not adopted this policy, he would, he says, have been faced with a deficit of about 50,000 marks. His gleeful comments on this transaction should act as a sobering corrective to the slogan of "making Germany pay" dinned into English ears. We take this opportunity to reiterate the statement, made on several previous occasions, to the effect that intending purchasers of German books should not rely upon the price in German marks given by the publishers. Often, if not always, the price charged for volumes exported is much higher; what it is can only be ascertained in any particular case by obtaining information from one of the firms of book importers in this country. Readers who may be purposing to visit Germany will no doubt have noted the statement issued at the end of last week by the Foreign Office explaining the stringent regulations enforced by the German customs officials on travellers leaving Germany. Briefly stated they amount to this, that a traveller leaving Germany is forbidden to take across the frontier goods purchased in Germany of a value exceeding 1,000 marks, nor more than 20,000 marks in German currency, or the equivalent in foreign currency, or cheques, bills, or negotiable instruments, except upon the production of a certificate of importation signed by the German customs authorities at the place of entry not more than one month prior to the date of export. The certificate of importation is good only for the actual currency imported. In Germany the policy of "making the foreigner pay" has indeed got well beyond the stage of the newspaper headline, and in the *Deutsche medizinische Wochenschrift* for July 14th there is a notice about the policy adopted by doctors in Berlin towards visitors from "valuta-rich" countries. With a view to creating a uniform system of fees for foreigners, doctors with a foreign clientèle in Berlin are instructed by their representative committee to exhibit in their waiting-rooms the following notice printed in four languages: "To Our Foreign Patients! The Doctors of Berlin, in Accordance with the Views of Their Foreign Colleagues, expect from Their Foreign Patients Coming from 'Valuta-Rich' Countries the Same Fees for Their Services as Would Be Paid by These Patients in Their Own Countries." To ensure the successful working of this scheme in every detail, the medical profession in Berlin has been supplied with scales of fees stated to be those generally charged in foreign countries, and a sliding scale has been devised so as to differentiate between various classes of patients and various classes of doctors, from the general practitioner to the professorial consultant. This sliding scale also shows the fees appropriate to the treatment of various diseases. The doctors of Berlin are also advised to settle the delicate question of fees before giving their services, and to see that they are paid in German currency. It may possibly be argued in defence of this policy that for a doctor to receive a fee of the dimensions of a tip to a waiter is not to maintain the dignity of the profession. But of the wisdom of this differential policy towards visitors in Germany there must be doubts, even from the point of view of the Germans themselves.

THE FRENCH MINISTER OF HEALTH.

At the luncheon given by the Government to M. Paul Strauss, the French Minister of Health, on August 10th, Sir Alfred Mond, who was in the chair, said that the main object of M. Strauss's visit had been to inspect a number of vacation schools which had received French children from the devastated areas as the guest of various municipalities; but he had taken the opportunity also of studying some aspects of public health administration in this country. French people had every reason to congratulate themselves on having a public man possessed of so large an experience and endowed with so much acuteness of mind to grapple with the difficult health problems left to their country as a legacy of the war. It had been a great pleasure to him to accompany M. Strauss on some of his visits; the Minister would take home with him assurance that the British people entertained the same

feelings of friendship and sympathy with their great ally across the Channel as the people of this country were confident the French people entertained for them. M. Strauss spoke very warmly in reply. He thanked the English people for their hospitality to French children from the devastated areas. The privations suffered by the population of those districts had produced a most serious effect upon their health; he quoted among other evidences of this effect the great increase which had occurred in tuberculosis. It was not, he said, the first occasion on which he had come to this country to study public health administration, but he had found much to interest him on the present occasion; he referred especially to his visits to Bromley, Portsmouth, and Dover, and thanked the municipalities for their readiness to help. Among those present at the luncheon were the French Ambassador, the Earl of Crawford (First Commissioner of the Board of Works), the President of the Royal College of Physicians of London, Sir George Makins, G.C.M.G., Sir George Nowman, Sir George Buchanan, Dr. F. E. Fremantle, M.P., and Dr. Nathan Raw, M.P.

HUMANE SLAUGHTERING.

A DECISION by the High Court, *Dodd v. Venner*, June 14th, 1922, has encouraged societies interested in the humane slaughtering of food animals to stimulate public interest in the subject. The usual method of killing cattle in this country is to knock them down with a poleaxe. In North and South America and in Australia a hammer is commonly used. Stunning by such methods, if done by an expert, must be accepted as humane, but unfortunately not all slaughtermen are experts, at any rate at the commencement of their careers as such. In this country sheep are almost always killed by cutting the throat, after which the spinal cord is dealt with, but consciousness continues for a time during the operation. Calves and pigs may or may not be stunned before slaughter. If not stunned they suffer after their throats have been cut until consciousness is lost as a result of cerebral anæmia. Nowadays the instruments recommended for this purpose are those which discharge a bullet into the brain of the animal to be slaughtered. A few years ago captive bolt pistols were recommended for the smaller animals, the stunning being effected by means of a rod, which was shot into the skull of the animal by discharge of a cartridge and automatically withdrawn therefrom by means of the recoil. The disadvantage of this kind of instrument was that, if not carefully attended to, the bolt was apt to jam, and at the present time the use of bullets is recommended; an instrument which discharges a bullet is, however, potentially dangerous to persons in the slaughterhouse unless properly handled. In 1915 the Local Government Board revised the model By-laws (Private Slaughterhouse Series), offering local authorities the option of adopting alternative clauses known as 9A and 9B. Clause 9A requires that specified kinds of animals must be stunned, effectively before slaughter. This requirement, as adopted by a local authority, nearly always excludes sheep, and quite often pigs also. Clause 9B provides that "a person shall not in the slaughterhouse proceed to slaughter any animal until the same shall have been effectively stunned, and such stunning shall, except as hereinafter provided, be effected with a mechanically operated instrument suitable and sufficient for the purpose." One of the provisos exempted sheep from the requirement for a period of three months from confirmation of the by-law. Animals slaughtered according to the Jewish method are exempted from the provisions of either clause; at the Metropolitan Cattle Market, Islington, some 80 per cent. of the cattle are slaughtered according to the Jewish method. The orthodox Jew, however, only eats the meat of the fore-quarter, so a considerable amount of the flesh of animals slaughtered according to the Jewish method is consumed by Christians. A meat inspector, however, pays attention to many matters not regarded as important from the standpoint of the Jewish ritual. A considerable number of local authorities, including

the County Borough of Reading, have adopted Clause 9n with the sanction of the Minister of Health. Early in 1922 a butcher in Reading, who was a bacon curer, declined to comply with By-law 9n on the ground that it was "unreasonable"—a valid objection in a court of law to a by-law, even though it had been sanctioned by the Minister of Health. The High Court, which is the ultimate court of appeal in this matter, decided that this by-law, if properly made, was "reasonable," and therefore enforceable by penalty; the case accordingly was remitted to the justices with instructions to convict. The societies mentioned are at the present time doing their best to persuade local authorities throughout the country to adopt Clause 9n, and the Minister of Health will no doubt resume his practice of sanctioning a by-law in that form. Efficient kinds of instruments are available for this purpose. For cattle the R.S.P.C.A. killer and the Greener gun are satisfactory; if properly applied there is no risk of accident. For sheep, pigs, and calves the Greeuer "Safety" pistol appears to be the best instrument at present available. Medical practitioners whose advice may be sought on this subject will be glad to be reminded that the form of by-law dealing with humane slaughtering allowed by the Minister of Health has been held to be reasonable on appeal to the High Court.

"MASTTUBERKELBAZILLENEINHEITSVAKZINE" AND OTHERS.

Few physicians have the time, opportunity, or inclination for following in detail the numberless publications dealing with the specific diagnosis and treatment of tuberculosis in the German medical journals. Whatever the quality of these publications, their quantity is imposing, and Dr. Baudelier and Professor Roepke¹ are to be congratulated on the courage and skill they have shown in collecting, summarizing, and reviewing all the recent German work on this subject in one volume. It weighs over 3 lb., but thanks to an orderly system of classification, and an index, it is fairly easy to find one's way and to get a bird's-eye view. Not only the number of specific remedies, but also the multiplicity of the methods of administration, is impressive. The physician has the choice of Koch's old tuberculin, albumose-free tuberculin, new tuberculin (T.R.), new tuberculin (B.E.), sensitized B.E., Selter's vital tuberculin, Landmann's tuberkulol, Klebs's, Rosenbach's, and Béraneck's tuberculins, Carl Spengler's perisuchtuberkulintherapie, Deycke-Much's partial antigen treatment, Friedmann's turtle vaccine, and Strubell's "masttuberkelbazilleneinheitsvaccine." There is also a liberal choice of serums, including Maragliano's, Marmorek's, Strubell's, Bruschetti's serum-vaccine, and Carl Spengler's "I.K." This list is very incomplete. The methods of administration are almost equally numerous—there are the cutaneous, percutaneous, intracutaneous, and subcutaneous routes, and each of these main routes can be subdivided almost indefinitely. Baudelier and Roepke are remarkably fair in their judgement; the case for and against each remedy is given in abstracts from original papers, and then the evidence is summed up. A favourable verdict is seldom given. This is perhaps inevitable, for the outstanding fact is that, while the specific treatment of tuberculosis in Germany has become more and more complicated and variegated, the morbidity and mortality have gone up by leaps and bounds since the beginning of the war. Overwork and under-feeding are forces against which laboratory ingenuity is practically helpless where tuberculosis is concerned. The impression left by the perusal of this work is that research in the specific treatment of tuberculosis has lately gone competitively mad, and that team work has given place—if it ever existed—to privateering of a sadly unproductive character. Each investigator has his following, and the competitive clamouring of the followers in different camps has done much to obscure the issues. Though the total amount of

work done is prodigious, it is only too obvious that an infinite capacity for taking pains does not always yield the fruits of genius.

LORD NORTHCILFFE'S DEATH.

THE death of Lord Northcliffe from a typical attack of infective endocarditis, while in the prime of his life and activity, is all the more deplorable because if he had realized the significance of the early symptoms from which he must have suffered it is practically certain that treatment could have been adopted which might perhaps have prevented the development of the complication from which he died. The acute disease to which he was a victim was due to an infection of the heart by a streptococcus, and was therefore of the severest type of this intractable form of disease of the heart, which on that account is frequently called malignant endocarditis. What seems probable is that he had, in fact, suffered from streptococcal infection for at least a year. The origin of the infection in these cases is often very obscure, but not uncommonly it can be traced to a septic infection around the roots of teeth, and it may be that this is how it began in Lord Northcliffe's case. However this may be, there can be no doubt that he had a general streptococcal infection and that eventually the blood was invaded. Very often the history of this extremely fatal form of endocarditis suggests that the infection, having reached the blood, attacks one of the valves of the heart which may have been damaged, perhaps by rheumatism, many years before. It is known that Lord Northcliffe had a cardiac murmur at least fifteen years ago; how long it had been present before that is not known. It is one of those incidental discoveries which are not of very much significance unless, as in his case, the damaged valve of the heart becomes infected. Although, as has been said, it is possible that he may have had symptoms of septic poisoning which could have been recognized a year or so ago had he then sought medical advice, the fact remains that until the heart was attacked by the infection he was not himself aware that anything was wrong. Remittent fever, with all its well-known accompaniments, exhausting the physical and mental powers of the patient, is one of the usual manifestations of the disease, which, in this instance, followed its almost invariable course, for it is one little amenable to treatment. The symptoms, as already said, were typical, and that sums up the case.

THE EDUCATIONAL NUMBER: NEW FEATURES.

THE Educational Number of the BRITISH MEDICAL JOURNAL for 1922 will be published on September 2nd; it will contain certain new features. We shall have the privilege of publishing an introductory article, contributed at our request by Sir Clifford Allbutt, on the training of the medical student, and another, by Professor W. E. Dixon, on the place of pharmacology in the medical curriculum. In view of impending changes several sections have been rewritten and much enlarged. A special article on the new era in medical education foreshadowed by the resolutions and recommendations of the General Medical Council, which will apply as from the beginning of 1923, will be published, together with details of these resolutions and recommendations. The concise information annually provided for intending students of medicine and newly qualified practitioners has been revised throughout, with the co-operation of the deans and secretaries of the various medical schools and kindred institutions in Great Britain and Ireland. Any members of the Association who may have got into the habit of looking upon the Educational Number as an annual guidebook to the profession which appears in the holiday season would do well to revise their ideas this year. The names of the authors of the two opening articles in our forthcoming issue of September 2nd are a sufficient indication that their words will appeal to a wider audience than the prospective student and his guardians. We mention this matter a fortnight ahead in order that no reader may overlook through inadvertence the important new features which will be found in the Educational Number of the BRITISH MEDICAL JOURNAL for 1922.

Nova et Vetera.

SYDENHAM.

THE classics of medicine are more talked about and less read than those of other ancient sciences, and there are good reasons for the neglect. The mathematician who is curious to know how theorems which he learned at school first saw the light has not to read Latin or even to wade through the collected works of defunct masters. Ostwald's *Klassiker der Exakten Wissenschaften* are available. At the cost of a few pence and a moderate knowledge of German he may read many of the best works of the best writers. The English medical practitioner in search of specimens of old and good professional works of pocket size has had Harvey on the Circulation available for some years, one work of Galen (in the Loeb series) since 1916, and now has Dr. Comrie's selections from Sydenham.¹ Dr. Comrie has done his work admirably. His volume is attractively produced; the illustrations are pleasing and the explanatory notes neither too concise nor overloaded with tedious erudition. No two students would be likely to agree as to what should be contained in an anthology—very likely some learned man will complain that Dr. Comrie has left out the best things; but the practitioner who puts Dr. Comrie's book into his pocket and uses the opportunities which this summer's weather is sure to supply will no longer have to take Sydenham's reputation on trust.

Nominally, Sydenham is one of the most accessible of classics. The old Sydenham Society's editions, Greenhill's text, and Latliam's translation are in every library and not scarce in the second-hand book market. But Latliam's translation is, as the author of *Rab* more than hinted, very dull, while the text is Latin—and, we think, remarkably unattractive Latin.

Why has Sydenham become immortal? Until now we should not have ventured to give reasons because the means of judging whether our reasons were right or wrong have not been in everyone's hands. Now, thanks to Dr. Comrie, anyone can tell whether we have hit the mark, so it may amuse Dr. Comrie's readers if we attempt to justify the title of "English Hippocrates" given to Sydenham.

We hope it is not irreverent to think that Sydenham is immortal because he applied to the art of medicine the spirit of Pauline Christianity set out in four verses of Corinthians (i, 22-25); he separated himself both from the Jews who require a sign and from the Greeks who seek after wisdom; he believed that "the foolishness of God is wiser than men, and the weakness of God is stronger than men."

The part of the Jew seeking a sign was taken by the physician who wearied his brains "with curious and irrelevant speculations, which to fulfil the promise of medicine, to save men's lives, are not worth anything," and the seekers of wisdom were "the slaves and followers who like the first inventors of speculations do deadly battle over these whimsies, while not a man of them reaches the truth, because however hard we try, we mortals cannot learn, and I think never will learn, how Nature acts, but only what she does and where she does it" (*Epistolary Dissertation*, 56). Sydenham believed that there was no vicarious salvation to be found by the physician; very little was to be learned from books—hence his advice to read *Don Quixote*—nothing to the purpose from what we now call the institutes of medicine, from anatomy and physiology. There is much in his attitude which recalls an earlier revulsion from the wisdom of this world; his "Nature" is the "God" of the Christian fathers, a wisdom not to be comprehended by mortals. At this time of day we are in small danger of being misled by the exaggerations into which his philosophy of medicine beguiled him. But there is some risk of our forgetting that his doctrine is fundamentally true, that a physician becomes really wise by the study of individual patients, that the reading of many books and the performance of many experiments in laboratories can never be substitutes for the "practice and that alone" which "elicits the indications of cure out of the phenomena of the diseases themselves" (*Epist. Resp.*, 1, 51).

We can all remember the sort of thing we did when we were clinical clerks. The medical registrar or the house-physician had entered on the bed sheet of the patient

"pleurisy with effusion," and we went home and looked up "Osler" and thereafter found in the patient the physical signs which he ought to show, but very often did not. This must be the way of beginners, but we need to guard ourselves from the habit of looking upon patients as the living "mories" of textbook descriptions, from the danger of being misled by the analogy of diseases with plants which may be "spotted" by aid of a textbook. Although Sydenham himself used that very parallel it never misled him in practice. "I confidently hold that the aforesaid species of disease, in particular the continued fevers, may vary so enormously that you may kill your patient at the end of the year by the method which cured sufferers at the beginning of it" (*Obs. Med.*, i, 2, 37). So it is not enough to identify your particular case of measles with the measles of "Osler" or "Taylor"; you must study your patients individually.

Some men of our time have dreamed that, whether by bacteriological, chemical, or perhaps physiological research, a great intellectual synthesis may be achieved, a new universal organon discovered, which will enable us to give an account of the changes of general and individual type of diseases, to foretell them, and so act appropriately. In the dialect of our theological comparison, such persons are like those who look for the immediate coming of the Kingdom of Christ. To Sydenham anything of the sort was an idle dream; whether what has been learned since his time is enough to warrant a change of attitude is a point which might be debated. But the discussion is idle, since, here and now, the method of Sydenham, the natural historical method of study, can be followed without hindering the work of those forging the organon. Were it permitted to Sydenham again to take coach exercise in Pall Mall and to visit the new homo of his old college, he would surely recognize that the "philosophers" had produced something better than "curious and irrelevant speculations," that Lister and Pasteur owed more to them than to him. But we think he would again enforce upon general practitioners the lessons of which the college physicians of his time stood in need, and perhaps think better of Sir James Mackenzie and his school than of the apostles of "Epidemic Constitutions."

"I am fully convinced," he would say again, "that, for the formation of right judgement in these matters, there is nothing so beneficial as the exact observation of the natural phenomena of the diseases themselves, likewise of whatsoever helps or hurts, and lastly of the remedies themselves and of the method we adopt to try to drive away the disease: By diligently examining and weighing all these I learn the nature of the ill and from whence I am to take indications of treatment. I learn it much better and much more surely than if I took some speculation concerning the nature of this or that principle as my pole-star. The choicest dissertations of this kind are no more than pretty tricked out metaphors which will go the way of all figments of the fancy, not grounded in the nature of things; time will utterly destroy them. The decisions of Nature, grounded in the truth of things, these shall not perish save with Nature herself." (*Tract. de Hydrope*, 25.)

Hippocrates said that philosophy must be wedded to medicine and medicine to philosophy, that the physician who is also a philosopher is evened with the gods (*De habitu decenti*, cap. 5). The puritan Englishman was humbler minded, but his gospel is one of encouragement, and its message is this: That way of "research" which is open to every doctor, which needs neither ultra-microscopes, nor knowledge of Greek, nor familiarity with differential equations, is the best way of all. Perhaps the greatest of all discoveries will not be made by the "consultant" whom we recently found so difficult to define, but by a general practitioner who brings to the research neither the contents of the *Index Medicus* nor the arithmetical wisdom of the Registrar-General and his assistants, but the brains with which Opie mixed his colours and the courage of Sydenham, together with his humility. This courage and humility, we think, justify Sydenham's reputation; whether we are in the right, Dr. Comrie's readers can judge for themselves.

PROFESSOR SCHAUMAN, of Helsingfors, who was well known for his studies on bothrioccephalus anaemia, pernicious anaemia, chlorosis, inequality of the pupils, and the etiology of a large sum for the foundation of a study of heredity.

THE French Minister of Health has organized a special commission to co-ordinate investigations as to the etiology, clinical study, treatment, and prophylaxis of cancer. The honorary president of the commission is Dr. E. Ronx, of the Pasteur Institute, and Professor Quénu is the acting president.

¹ Selected Works of Thomas Sydenham, M.D. With a short biography and explanatory notes by John D. Comrie, M.A., B.Sc., M.D., F.R.C.P. Edin. 1922. London: Bale, Sons, and Danielsson. (Pp. 155. 6s. 6d. net.)

THE PHYSICAL EDUCATION OF GIRLS.

At the instance of the College of Preceptors a Joint Committee was formed in October, 1921, to consider the effects of physical education on girls. Representatives were appointed by the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association (Mr. E. B. Turner and Mr. R. C. Ehmslie), the Medical Women's Federation, the British Association for Physical Training, the Ling Association, the National Union of Women Teachers, the Association of Assistant Mistresses in Secondary Schools, the Private Schools Association, and the College of Preceptors. The Association of Head Mistresses did not accept the invitation to send representatives.

The Committee issued a paper of questions to persons who might be expected to have special knowledge of the subject. Altogether 629 replies were received, and of these 233 were from medical practitioners and 158 from women medical students; 185 replies came from headmistresses, 96 from State-aided schools, and the others from independent schools. A report of an investigation by the Ling Association was also considered. A special set of questions were sent to medical practitioners and their replies submitted to a committee consisting of the medical members.

Amongst the schoolmistresses there was a general consensus of opinion that the effects of games and physical exercise on the disposition and character of girls were beneficial; but a small number thought there was a tendency to magnify the relative importance of games, to the detriment of character.

The question whether gymnastics with apparatus is suitable for girls was specially inquired into; about 66 per cent. of the schoolmistresses were in favour of such gymnastics, but about half of those who approved were of opinion that there was special need for careful supervision if apparatus was used. Amongst women students, medical or otherwise, 80 per cent. were in favour of the use of apparatus. Very few harmful results were attributed to it, though some, especially among the women students, thought that such gymnastics conducted to muscular strength and development without gracefulness. Gymnastics without apparatus was approved alike by mistresses and by students, medical or otherwise, though a few considered such training as less valuable than gymnastics with apparatus. The need for fully qualified gymnastic teachers was emphasized.

Of games, lawn tennis and netball received very general approval; hockey, though approved by the majority of mistresses and students, was regarded by some as suitable only for the older and stronger girls and by some as too rough or strenuous a game for girls. Several objected to it as inducing faulty positions.

Very little serious objection was raised to cricket; some of the disapproval expressed was based on the ground that it entailed too much standing and might thus induce faulty carriage. Lacrosse was approved by almost all who offered any information about it. Football met with less approval than any other game; of fifty-two schoolmistresses who expressed their views on this game, only two were in favour of it, and among women students, though a few approved, many more objected to it on physical or other grounds; in general it was regarded as entailing too much strain.

Swimming was generally approved, but many schoolmistresses and students recognized that harm might be done by remaining too long in the water and that swimming was an exercise entailing some strain on the heart, so that it is not suitable for all girls. The danger of heart strain was emphasized even more in regard to rowing, which, though approved by the majority of those who gave information on the subject, was thought by some to be too strenuous an exercise for girls in general. Racing in rowing was condemned by twenty-seven out of thirty-four women medical students, and ill effects were recorded. Cycling in moderation, the cycle being properly adjusted to the individual, met with a large measure of approval; some schoolmistresses pointed out that when girls have to cycle too long a distance to school, the strain makes them unfit for mental work. The value of dancing was generally emphasized, eurythmics were approved by some, whilst others were in favour of horse-riding, fencing, golf, badminton, or fives.

Contests in games and sports were thought by many to require careful limitation and grading with a view of preventing overstrain.

There was very general agreement that ill effects would be

less likely to occur from the more strenuous forms of physical education if previous medical examination were more general, and that the risk of such effects could be reduced if a short time was devoted to games or sports daily rather than a longer time once or twice weekly. Girls should not be subjected to strenuous physical exercises after hours of mental strain, and ample time should be allowed for rest after games and sports before beginning mental work again; facilities should be given for changing underwear after strenuous games. A wise and sympathetic tact is an essential factor in adequate supervision by the games mistress.

It was found difficult to summarize the opinions held as to the general, physical, and mental effects of games and sports upon girls. By many it was thought that apart from physical fitness they conduce to alertness, resourcefulness, and judgement, and encourage a public-spirited and healthy outlook. On the other hand, a minority thought that games and sports tended to foster a love of pleasure, detrimental to home and other interests and to lessen womanly qualities.

Medical Report.

The opinion of the medical members of the Committee, after consideration of the information before them, was as follows: Suitable physical education, including games and sports, is as generally beneficial to girls as to boys. There is, however, need for discrimination; individual girls may be unfit for particular forms of exercise, and on this account medical examination as to fitness is generally desirable.

Amongst the games the committee had under consideration, tennis, netball, lacrosse, golf, hockey, cricket, and football, only the last is considered unsuitable for girls. Of sports, swimming, rowing, cycling, horse-riding, are all good for girls, provided that they are carried out under suitable conditions and excess is avoided. Competitive games and sports are equally permissible, provided they are undertaken with due regard to the fitness of the individual.

Any game or sport may become unsuitable if practised in such a way or to such degree as to cause undue strain or fatigue. There is a balance between mental exertion and physical fatigue which cannot be altogether ignored. A girl who is working at high pressure for examinations may have to play games less strenuously, and fatigue by physical exercise is a bad preparation for mental work.

With regard to gymnastics, whether with or without apparatus, there is no doubt of the value of disciplined exercises under expert direction for promoting the harmonious development of the muscles and preventing faulty position and carriage. The use of apparatus entails special care, as injurious effects may come from injudicious exercise of this sort.

An important question in connexion with the physical education of girls is whether and to what degree there should be restriction of physical exercise during the menstrual period. Abstinence from games and sports has been very generally recommended hitherto, but in recent years evidence has been brought forward to show that these restrictions are harmful rather than beneficial. The medical members of the Committee are not prepared at the present time to state any final judgement on the question, but consider that the evidence they have justifies more extensive trial of the voluntary continuance of games, sports, and gymnastics (swimming excepted) during the menstrual period.

The disturbance of functions so often observed during school life occur also in girls who do not take part in athletic pursuits, and the influence of physical exercises on these disturbances is quite open to doubt. The production of any internal displacement is probably very rare.

Perhaps the most important point which arises in connexion with the physical education of girls is its influence in after-life, if any, upon motherhood.

It is difficult to obtain conclusive evidence on this point. It might be thought that the increased muscular and bone development consequent on much physical exercise might increase the difficulties of parturition, and, whether for this reason or not, labour has been thought by some to be lengthened in such cases. On the other hand, the increased muscular power might serve to facilitate parturition, and some observers have attributed a good result in this way to strenuous physical education.

On the whole, it would seem that there is no clear proof that strenuous physical education has any special influence either upon the prospect of motherhood or upon the difficulty of labour.

The conclusions reached by the Joint Committee may seem less precise and positive than might be expected, but the Committee felt that the evidence available was not such as to justify dogmatic statement on many of the points under consideration. Nevertheless, they hope the investigation may not have been without value if it draws attention to the important problems of the physical education of girls, and particularly if it serves to stimulate further research, and to encourage the collection of what is much needed—namely, well attested facts and observations.

Signed on behalf of the members of the Joint Committee,
G. F. STILL, *Chairman*.

SHELL SHOCK.

THE report of the War Office Committee of Inquiry into Shell Shock¹ issued last week is a document which may well interest the general reader as well as those members of the military and medical professions to whom it makes a mere direct appeal. It may be said at once that the Committee has been successful in producing a report of which it can be asserted that it deals with every aspect of a very important problem. Throughout the report the use of the term "shell shock" is deprecated as conducive to much misapprehension, and the Committee decided to divide the cases into three categories: (1) true commotional disturbances; (2) emotional disturbances; and (3) mental disorders. Owing to the prohibitive amount of labour and expense involved in their preparation statistical details are not included, and we agree with the Committee that this omission is not a serious fault.

After an interesting preliminary in the shape of an historical memorandum from the pen of the Hon. John Fortescue, we are introduced to a summary of the evidence of some of the many witnesses examined; these included combatant officers, both staff and regimental, medical officers of regiments as well as neurologists attached to special shell-shock treatment centres, several of the consulting physicians lately attached to the armies in the various war areas, and finally a large number of distinguished medical men who were responsible for the treatment in this country of cases of shell shock and other nervous disorders. The evidence also of certain patients suffering from the condition was included.

Etiology.

Sir John Goodwin was emphatic on the value of good discipline and training in the prevention of shell shock, while General Lord Hume agreed with the usual regimental opinion that a large number of shell-shock cases in a battalion was a sign of poor moral.

Professor Roussy laid stress on the hereditary or constitutional factor in many cases exhibiting psycho-neuropathic affections, and considers that mental defects were very often to be found among the hysterical cases. Dr. Burton Fanning's evidence on the frequent occurrence of the neuroses in the Home Forces had the effect of emphasizing the emotional factor in the etiology. Dr. Hurst's experience of neurasthenia in the Eastern theatres of war exemplified the important part played by infections and exhaustion; he agreed also as to the great difficulty of distinguishing clearly in some cases between neurosis and simulation. It is quite impossible to review in detail all the evidence brought forward; many facts of great practical value emerge from its study, especially that of the combatant officers and of those medical officers whose duties lay in or near the front line. Here we find a consensus of opinion that a poor moral and defective training are one of the most important, if not the most important, etiological factors; also that shell shock was a "catching" complaint—so much so, indeed, that in the Ypres salient the Guards refused to go into the line with a certain battalion next them.

The influence of fear, again, is a cause upon which all witnesses were agreed, especially in regard to the mental conflict engendered between the natural fear on the one hand and the duties of discipline and patriotism on the other. The fact that the neurosis serves a purpose—that is, removal from the danger zone—is brought out clearly in the evidence.

All the witnesses were agreed that the cases belonging to the class of true shell concussion were few; emotional shock was the commonest cause, to which was to be added a general nervous and mental exhaustion as the result of the prolonged strain and hardships. Thus Dr. Gordon Holmes found that

between 4 and 10 per cent. of the cases were commotional; Dr. Johnson found 5 per cent. of commotional cases, 1½ per cent. only of cases showing lesions of the central nervous system, and 1 per cent. of cases with rupture of the drum of the ear.

There was a general consensus of opinion, again, that neuroses were common as the result of the action of poison gases, especially by the production of conversion hysteria.

Shell Shock as Battle Casualty.

Regarding the important practical question as to whether shell shock should rank as a battle casualty or not the Committee makes the following recommendations:

1. That concussion or commotion attended by loss of consciousness and evidence of organic lesions of the central nervous system or its adjacent organs (such as rupture of the membrana tympani) should be classified as a battle casualty.
2. That no case of psychoneurosis or mental breakdown, even when attributable to a shell explosion or the effects thereof, should be classified as a battle casualty any more than sickness or disease is so regarded.
3. That in all doubtful cases it is desirable to have the classification determined by a board of expert medical officers after observation of the patient in a neurological hospital.

Treatment.

Questions as to the best treatment elicited a majority of opinion to the effect that cases should be kept as far as possible in the divisional areas and not invalided home; experience of cases treated for long in home hospitals showed that seldom were such men able to return to the line.

The value of the regimental medical officer is insisted upon, and it is further stated that he needs no special neurological knowledge; one witness insisted that "an intimate knowledge of human nature" was the most important requisite, a fact which few could be found to dispute.

As far as the actual methods of treatment are concerned we find that the majority of witnesses were not in favour of the Freudian method of analysis, but rather of the more simple methods of persuasion and explanation. The value of occupation and re-educative exercises was insisted upon. Indiscriminate sympathy from the general public is deprecated. Another important point in treatment is the harm done by the frequent transfer of a patient from one hospital to another, with the result that no consistent line of treatment can be adopted.

The Committee lays down recommendations under which a soldier should be returned to the line, and perhaps this may form a guide for future use.

It is pleasant to read the conclusion that true malingering was probably of rare occurrence, but the Committee goes on to say that exaggeration of symptoms or the prolongation of a condition that no longer really existed was far from uncommon, and that such a form of partial malingering was very difficult to deal with.

Shell Shock and Insanity.

Much has been written in the general press of the cases of, insanity supposed to be due to shell shock. This supposition receives no support from the witnesses who were examined on this point. Dr. Stanford Read adds the significant statement that of the service patients now in asylums the majority in his opinion are suffering from dementia praecox. Professor Roussy says in the same connexion that the war created nothing in the way of the psychoses.

Prevention of Shell Shock.

The prevention of or the lessening of the incidence of shell shock is a subject which receives much attention, and it is highly significant that the first factor regarded as tending to increase the incidence and severity of mental and nervous disorders in time of war is the perpetuation of the term "shell shock."

Important conclusions are detailed in regard to the great importance of good discipline and moral, in fact of a thorough and careful training, as prophylactic measures in the prevention of the condition. The value of adequate rest away from the line is another point upon which much stress is laid. Methods of recruiting, both in time of peace and war, are dealt with at some length, and the difficulties and deficiencies discovered by the war are fully described.

One conclusion reached in this connexion is that not enough attention has been paid to the mental and psychological aspects of military service.

There are three appendices, giving the questions issued for the guidance of witnesses, tables of statistics of cases of neurasthenia treated in the Neurological Department of the

British Salonica Force, and outlines of the principles of training considered desirable in the prevention of shell shock.

The report is one which in all its parts will amply repay careful study.

THE HEALTH AND HEALTH ADMINISTRATION OF ENGLAND.

A PRELIMINARY notice of Sir George Newman's report for 1921¹ on the State of the Public Health appeared in our issue of August 5th. The report is exceptionally short, but it takes note of all parts of the field of public health work in England and Wales. Its brevity makes possible, by further condensation, the presentation to our readers of an epitome of the health administration of England sufficiently short for convenient perusal and yet inclusive enough to avoid omission of anything of primary importance. It is very desirable that every practitioner of medicine should realize the scope and the variety of detail in modern work as carried on in this country for the maintenance of health and the prevention of disease.

The order in which the essentials of preventive medicine are stated in this report is unusual. To develop and fortify the physique and powers of the individual comes first; next we must seek to discover and then to prevent or remove the causes and conditions of disease, whether concerned with domestic or industrial environment or personal habits. As urbanization advances the fundamental necessities of a healthy community can only be provided by itself.

A Ministry of Health as a central co-ordinating department was proposed by Sir John Simon in 1854, but was established only in 1919. In addition, the country requires local authorities, voluntary agencies, the medical profession as instrument and interpreter of hygiene, and an educated people willing and able to practise the way of health. The voluntary element is invaluable, and not the medical profession but the local authorities, representing the people, must control expenditure. Wise expenditure is like a lifeboat or a fire engine, and is besides a long-term investment, yielding a thousandfold, but only in course of years or generations. Millions of persons in Russia and elsewhere died in 1921 because there was no sanitary service to save them. Wise expenditure is true economy. Here the author changes the order already noticed. "A sanitary environment and education in hygiene which affect the entire population obviously stand first." Next are maternity and child welfare, the health of the school child, industrial hygiene, the prevention and treatment of disease, both infectious and non-infectious, and research.

THE STATE OF PUBLIC HEALTH.

The birth rate in England and Wales in 1921 was 22.4, a decline of 3.1 from the previous year, but the 1920 rate was exceptionally high as a reaction from the war years. The death rate fell from 12.4 to 12.1, the lowest on record. The following table gives the figures for the principal causes of death:

England and Wales: Deaths from Principal Causes, 1921.

Disease.	Number of Deaths.	Proportion per 1,000 Deaths from all Causes.
Measles	2,241	5
Whooping-cough	4,576	10
Diphtheria	4,772	10
Influenza	8,995	20
Tuberculosis of respiratory system	33,526	73
Other forms of tuberculosis	9,173	20
Cancer	46,022	103
Diseases of nervous system and sense organs	48,217	105
Disease of the heart	53,707	117
Other diseases of circulatory system	14,571	32
Bronchitis	33,684	73
Pneumonia	34,703	76
Other diseases of respiratory system	5,707	12
Diarrhoea and enteritis	17,035	37
Other diseases of digestive system	18,328	40
Diseases of genito-urinary system	17,852	38
Prenatal birth and diseases of early infancy	26,442	58
Old age	27,405	60
Violence (all forms)	16,501	35
Other causes	35,155	77
Total	458,628	1,000

¹ On the State of the Public Health. Annual Report of the Chief Medical Officer of the Ministry of Health for 1921. H.M. Stationery Office: to be obtained through any bookseller. (Pp. 115. 1s. 6d. net.)

Infant Mortality.

Infant mortality was 83 per 1,000 births. This is higher than in the previous year, when it was 80; yet is even more satisfactory, looking to the hot and dry summer of 1921. The diarrhoea and enteritis rate under two years rose from 8.3 to 15.5, yet the total rate, including these figures, rose only by 3, so that in deaths from other causes there was a decided fall. A table given later in the Report shows the great progress made since the beginning of the century in diminution of deaths of infants. In the first four weeks of life, however, there has been little improvement. That age period has not yet come under effective control, no doubt owing to constitutional defect, part of which is due to insufficient antenatal attention; among illegitimate infants the rate was as high as 158 against 83, and the reasons are unfortunately easy to find.

Adult Mortality.

The lessons of the English life tables for the two periods 1838-54 and 1910-12 (unfortunately the latest available) are that the average lifetime of males has increased from 40 to 51 years, and of females from 42 to 55 years. But this is made up of a higher rate of improvement in the early years, and a lower in the later, so that at the age of 45 the extension of male expectation had only been from 22.76 to 23.92 years, and at 55 the condition was stationary. Sweden is much better off; at 45 a man there has three more years, to look forward to than in this country, and at 55 the same difference exists. It was not always so. The Swedish expectation used to be lower than the English. Our largest single cause of death at these ages is pulmonary tuberculosis, and its decline has been much slower than in the earlier age groups. Respiratory diseases, including pneumonia, come next, and here manufacturing Lancashire has a bad pre-eminence not to be explained wholly by climate, as Cumberland is much lower. Neither is poverty the reason. Incomes in Bolton and Warrington, as shown by Professors Bowlby and Burnett Hurst for 1911-13, were a good deal higher than in the industrial town of Reading, yet the Reading death rates were much lower. Though there is more overcrowding in the two Lancashire towns, that can hardly account for Reading's more favourable health position; it has more overcrowding than Northampton, and yet has a lower death rate.

In summing up Sir George Newman does not profess to put his finger on the exact causes of the statistical facts. After discussing various relevant considerations he says:

"Yet neither by physique alone nor by ventilation of workplaces alone will a security against disease be afforded. Temperance in food and drink is not alone a perfect defence. It is by the accumulation of all these safeguards, by temperance in food and drink, by the cultivation of good habits of body, by rational attention to the environment both of the workplace and the home, that an enduring defence against not one but all forms of disease is created."

Sickness and Invalidity.

Statistical tables of infectious disease for 1921, which, excluding tuberculosis, are responsible for about 10 per cent. of mortality, are followed by a brief consideration of sickness and invalidity. Two sets of data exist, one relating to school children, the other obtained from statistics supplied under the National Insurance Act. The number of school children inspected in 1921 was, in round numbers, 2,500,000, and about 40 per cent. were found with defects. The chief types of defect were malnutrition (3 per cent.), nose and throat disease (15 per cent.), enlarged glands (6 per cent.), serious dental disease (20 per cent.), anaemia (3 per cent.), deformities, defective hearing, and skin disease (2 per cent. each).

Under the Insurance Act the average annual amount paid for sickness and disablement benefit for men during the last nine years was £4,208,720. These figures represent a total of 9,163,613 weeks of incapacity; for women the corresponding figure is 5,312,461 weeks. The total for both sexes every year is more than 278,000 years of lost time, or the work of 278,000 persons for one year. Data selected from a special investigation of 226 practices in 116 towns give the causes of incapacity in 36,325 cases of illness, and the following table (p. 324) states the results.

Minor maladies, it will be observed, are more notable than tubercle, cancer, or organic heart disease. This fact, taken with all the ailments which do not cause unfitness for work, but in which the doctor is consulted, indicates the opportunity which the Act affords for the practice of preventive medicine.

Insured Persons in Representative Cities—Proportion of Certain Diseases to Total Cases—1916.

Disease.	Total.		Male.		Female.	
	No.	Per 1000 of Total.	No.	Per 1000 of Total.	No.	Per 1000 of Total.
Influenza	3,097	85.3	2,034	93.2	1,093	77.5

Maternity and Child Welfare.

Maternal deaths from sepsis in childbirth have ranged from 2.18 per 1,000 births in 1920 to 1.45 in 1921. The movement is irregular, but is in the right direction. From causes other than sepsis the lowest year was 1908 with 2.09, and the highest 1900, with 2.63, but there is really little perceptible change. Of the 3,323 deaths in 1921 the main causes were sepsis (1,171), albuminuria and convulsions (604), haemorrhage (469), other accidents of childbirth (383), and embolism and sudden death (262).

Last year's hot summer supported Ballard's observation that infantile diarrhoea does not begin until the earth thermometer at 4 ft. shows a temperature up to or over 56° F. Factors of importance no doubt are cleanliness, destruction of flies, and the use of dried milk where storage is defective.

The special value of the education of mothers is testified from many districts. For economy's sake now child welfare centres are not being established. As regards the policy to be followed at existing centres, it is evident that the Ministry's experience is leading it in the same direction as in the United States. Treatment is not its function. There should be no giving of prescriptions, nor routine sale of medicines even when paid for at cost price. The sale of foods should be limited to cases in which they are ordered by the doctor and the mother cannot afford to get the article in the usual way. The distribution of free milk through the centre should be avoided as far as possible. In short, it is italicized that the centre's main functions should be "the supervision of the healthy infant and the education of the mother." That is a very important declaration of administrative policy and is on thoroughly sound lines.

Health Visiting.

The number of whole- or part-time health visitors employed by local authorities in England and Wales was 3,378. About 74 per cent. are trained midwives and 67 per cent. trained nurses. "Their work may be of great value or practically useless, according to the way it is carried out," and "no visit can be of real value unless the visitor appreciates its purpose and possibilities and goes about the business of making friends with and of teaching the mother in the right way." No attempt is made to state what proportion of the work approximates to the principle thus set forth, but the emphasis given to it makes clear that the Ministry is of opinion that the work is not universally well done.

Infant Hospitals and Observation Wards.

About forty-five infant hospitals and observation wards have been recognized. They are intended for the less serious but more chronic type of case which cannot remain in the ordinary hospital yet needs institutional treatment, and the number of beds is limited. Once more the educational note struck. "It is also desirable that the mother shall be taught how to manage her child when it returns home."

In the course of some comments on auxiliary services—day nurseries, homes for healthy babies and for unmarried mothers—it is pointed out that young children should as far as possible not be placed in institutions. Good foster-mothers are the best, and small cottage homes come next. This was the line taken by the Royal Commission on the Poor Law. Homes for unmarried mothers are not being fully utilized; girls cannot be persuaded to stay in them long enough; it may be necessary to close some homes or to use them for different purposes.

(To be continued.)

Scotland.

MILK ADULTERATION IN EDINBURGH.

THE Scottish Board of Health has issued its report on the administration of the Food and Drugs Acts during the year ended September 30th, 1921. Most local authorities give a good deal of attention to sampling and analysis, but in some places only a few articles are sampled, and in others the work is confined to milk. In certain areas samples are taken on only one or two days in the year, but these observations do not apply to the large centres or more important county areas. Of 6,327 "formal" samples (purchased for legal action if necessary) 514 were reported against. In the previous year the corresponding figures were 6,430 and 591, so that the percentage fell from 9.2 to 8.1. Of milk 4,418 samples were analysed, and of these 402, or 9.1 per cent., were found adulterated. The great bulk of them were of new milk, but among a few samples of skim milk, butter milk, and cream powder a certain number were found adulterated, whilst all of the few samples of condensed milk were genuine. The most remarkable fact about the figures is the extraordinary percentage of adulteration in Edinburgh. Whilst Dundee, Glasgow, and Aberdeen had 8.8, 7.3, and 5.8 per cent. respectively, Edinburgh had the amazing figure of 39.6 per cent.—that is, of every five samples taken two were not genuine. Surely the town council of the capital of Scotland will have something to say to this smirching of its fair fame. From the tables we find that the milk samples taken in Edinburgh numbered 149; 59 were adulterated, so that the high percentage cannot be excused as a chance result from insufficient data. In London, as shown in the Report of the Ministry of Health, the percentage of milk adulteration was only 5.1, whilst that for the whole of England was 8.6; the capital, therefore, was better than the provinces, whilst in Scotland the position was very much the reverse.

As to butter, 34 of 411 samples taken were adulterated, but only one of 202 margarine samples was not correct.

Egg powder is specially reported on by Dr. Tocher of Aberdeenshire. Basing his remarks on nine samples he says:

"Results show that the powders contain none of the constituents of eggs, and that therefore the title 'egg powder' is a misnomer. It is well that the public should know the composition of such 'egg powders,' so that purchasers may not be misled into thinking that the powder is in any sense an article of food. The statement that egg powder is the only real substitute for eggs is not warranted from the results of analysis, although the 'egg powder' may possibly be quite useful as a raising agent or for other purposes in cooking."

Among the 191 samples of drugs taken 11 were reported against; of the 191 no fewer than 118 were of cream of tartar, so that only 73 samples of other drugs were taken throughout Scotland, and the Board considers that this reveals very insufficient sampling. Mixtures of malt and cod-liver oil are the subject of an important paragraph. A certificate of analysis of one sample showed the percentage of oil to be only 2.82, while according to the B.P. Codex it ought to be 50, and the extract of malt with cod-liver oil should contain 15 per cent. of the oil. The Board communicated with the General Medical Council and received the reply that the question of including in the *British Pharmacopoeia* an emulsion of cod-liver oil and of an extract of malt and cod-liver oil would be considered during the preparation of the next edition, or earlier if an addendum to the *Pharmacopoeia* should become necessary. The report concludes with a series of statistical tables.

THE CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The report on the work of the Central Midwives Board for Scotland for the year ended March 31st, 1922, is signed by the president (Dr. James Haig Ferguson) and the secretary

(Mr. D. L. Eadio), and contains indications of considerable activity—for instance, the Board had thirty meetings (including committees) during the year; down to March 31st 452 midwives were enrolled after passing the examination of the Board, 7 were certified in virtue of *bona fide* practice, and 15 by approved bodies, making a total for the twelve months of 474, which, added to the previous enrolments 4,548, gave a grand total of 5,022. Of this total the larger part consisted of the 3,292 who had been admitted in virtue of certification under Sections 2 and 11 of the Midwives (Scotland) Act of 1915—that is, through holding recognized certificates or in respect of having been in *bona fide* practice at the passing of the Act. The number admitted under these sections is year by year dwindling, and before long they will cease. As evidence of reciprocity between the three parts of the British Isles it was noted that during the past year fourteen midwives holding the certificate of the Central Midwives Board for England after examination and one midwife holding that of the Central Midwives Board for Ireland after examination had been admitted to the Roll in terms of Section 11 of the Act. Nine midwives died during the year.

There were four examinations as usual at three of the centres—namely, Edinburgh, Glasgow, and Dundee—and three at Aberdeen. The greatest number of candidates (247) appeared at Glasgow and 32 were rejected, or 12.95 per cent.; the next largest number (198) were at Edinburgh, where 19, or 9.59 per cent., failed; 100 per cent. of the number (35) at Dundee succeeded in satisfying the examiners; and 4 out of 27 failed at Aberdeen (14.28 per cent.). The average of rejections worked out at 10.86 per cent.; and it was gratifying to find that the pass marks secured by the successful candidates averaged 62 per cent. of the possible. The statement appears in the report that "the Board have continued the regular system of visitation of examinations by selected members of the Board which was instituted last year and it has been found to be beneficial alike to examiner and candidate."

The penal cases were not numerous. As the result of the hearing of the charges the names of five women were removed from the Roll, while in addition three were prohibited from attending women in childbirth in any other capacity. In two of these instances the offence charged was that of failure to send for medical assistance in cases of inflammation of the eyes of the child and failure to notify these cases; in other instances failure to send for medical assistance in the cases of rupture of the perineum, *post-partum* haemorrhage, failure to notify contact with patient suffering from puerperal fever, failure to attend during full period of the puerperium, and in one case leaving the patient before the expulsion of placenta and membranes. There were two suspensions from practice for three months; and a large number of cases of minor offences were dealt with by warnings sent through the medical officers. Prosecutions against women who had been practising as midwives without having been enrolled or after having been struck off had been successfully instituted by the officers of the local supervising authorities, and had had a salutary effect in reducing unqualified practice in certain areas.

An interesting fact noted by the Board was that the practice of midwifery in certain districts was falling largely into the hands of midwives. There were, however, wide differences. In two places (Cockenzie and Prestonpans) 100 per cent. of the total births (probably not many in all) were attended by midwives; in Cowdenbeath, Port Glasgow, and Tain the percentage was from 80 to 90; in Dalkeith it was 75 per cent.; in Glasgow it reached 48.85 per cent.; in Bathgate it was 16.5, in Edinburgh 8.3, and in Moray County only 1.5. These differences point to interesting fluctuations in the distribution of practice between doctors and midwives, not always explicable on general principles. Some interesting statistics are supplied relative to the number of cases in which medical assistance was called in for emergencies, and to the number of cases of ophthalmia neonatorum, of puerperal septicaemia, and of stillbirths.

After meetings with representatives of the Scottish Board of Health, the Board decided, in connexion with the occurrence of ophthalmia neonatorum, to insert a rule making provision for midwives in all cases dropping a 1 per cent. solution of nitrate of silver or other approved silver preparation into the infant's eyes as a preventive. Appendices give the list of institutions at which midwives may be trained and the names of the examiners recognized by the Board.

CONVALESCENT HOSPITAL FOR EDINBURGH.

The Edinburgh Royal Infirmary has (since 1867) had a convalescent hospital at Corstorphine with eighty beds; but through the setting free of a large sum of money left some twenty years ago by the late Mr. David Ainslie of Costerton, East Lothian, now beds for this purpose will soon be available. Mr. Ainslie left instructions that the money was to accumulate for fifteen years, and that then the principal and accumulated funds were to be used to construct a convalescent hospital to be called the Astley-Ainslie Institution. The fifteen years expired some time ago, but the prohibitive cost of building materials and labour delayed progress; now, however, a beginning has been made with the purchase, for a sum of about £70,000, of certain beautifully situated properties in the southern suburbs of Edinburgh. They cover about 25 acres and consist of Canaan House, Canaan Park School, Millbank and Southport Houses, and a ladies' golf course. When all the residences are completed there will be room for between 300 and 400 persons; but in the meantime only the school is to be prepared for use. It will provide accommodation for 50 convalescent women patients along with nurses and staff, and it will be ready by the beginning of 1923. The Governors of the institution will be appointed as follows: five by the Managers of the Edinburgh Royal Infirmary, one each by the Court of Session, the Royal College of Physicians, the Royal College of Surgeons, the Merchant Company, the Chamber of Commerce, the Chartered Accountants' Society, and the Church of Scotland Presbytery of Edinburgh.

England and Wales.

WELSH BOARD OF HEALTH.

The Minister of Health has made the following appointments (unpaid): Captain Ernest Evans, M.P., to be a member of the National Health Insurance Joint Committee; Professor Ewen J. Maclean, M.D., F.R.C.P. Lond., F.R.S. Edin., J.P., to be the Chairman of the Welsh Consultative Council.

MILK PROSECUTIONS.

We referred at length on August 5th (p. 232) to Circular 325 issued by the Minister of Health with regard to prosecutions for selling milk deficient in fat. The matter has been under the consideration of the Special Committee on Foods of the Society of Medical Officers of Health, and its report was adopted by the Society at its annual provincial meeting at Bournemouth on July 28th. The circular of the Minister of Health recommended that in cases of milk adulteration prosecutions should be instituted only where a series of tests have shown repeated default. The Society in adopting the report of its Committee expressed its regret that such a circular should have been issued and its hope that the Minister on reconsideration will withdraw it. The Society is of opinion that the circular presents no advantages except to the unscrupulous milk dealer. "The honest trader," the report continues, "is amply protected since local authorities are always willing to consider exceptional circumstances. If he still feels aggrieved after a decision (it should be noted that the standard with which a milk seller is required to comply is only one of *presumption*), provision exists whereby, in such instances as those enumerated in the Circular, the milk seller may submit proof to the magistrate, in case of prosecution, that the circumstance is one arising from natural causes and not from wilful tampering with the milk." The report concludes by expressing the opinion that certain of the effects of the Circular will be as follows:

(a) Some unscrupulous dealers will take advantage of the concession and continue to extract fat from, or to add water to, milk until that series of tests which will show "repeated default" has been obtained.

(b) The probability of a positive series being obtained within a brief period will be decreased if the milk seller ceases to adulterate for a time after a positive result has been obtained. Such intermittency will reduce the probability of default being detected; or with the same intention such milk seller might only reduce the quality of the milk on certain days with obvious effects on the health of the infants.

(c) The circular cannot always be carried out, and the effects of the circular in the case of positive results being thus obtained they can be used in court as evidence of "repeated default."

(d) Milk is the most important food of infants, and of many invalids, and inferior milk may continue to be supplied with the

knowledge of the local authority to certain persons to their serious detriment—that is, during the time the series of tests to prove "repeated default" are being obtained.

(c) The Food and Drugs Acts were never intended to bear this generous trading concession, and if such applies to the milk seller it ought to be held to apply to every other trade sample.

Victoria.

THE AUSTRALASIAN MEDICAL CONGRESS, BRITISH MEDICAL ASSOCIATION.

THE Australasian Medical Congress, which formerly met triennially in the capital cities of Australia and New Zealand, has been reconstituted as an Australasian Congress of the British Medical Association. The first session under the new conditions is to be held in the University of Melbourne from Monday, November 12th, to Saturday, November 17th, 1923, under the presidency of Mr. G. A. Syme, F.R.C.S. The general secretary is Dr. A. L. Konny, 13, Collins Street, Melbourne, to whom all communications should be addressed. Members of the British Medical Association in Great Britain and Ireland, who may find it convenient to take a long holiday in Australia, will be particularly welcome at the Congress, and may be assured of a generous hospitality. As the great Melbourne Cup Race Carnival commences on Saturday, November 3rd, and terminates on Saturday, November 10th, overseas visitors to the Congress will be able to combine pleasure with business. Further, November is one of the most delightful months of the Australian spring. The sections of the Congress comprise Medicine, Surgery, Obstetrics and Gynaecology, Pathology and Bacteriology, Preventive Medicine and Tropical Hygiene, Ophthalmology, Otology, Rhinology and Laryngology, Neurology and Psychiatry, Diseases of Children, Naval and Military Medicine and Surgery, Dermatology, and Radiology and Medical Electricity. The names of the presidents and secretaries will be announced later.

POST-GRADUATE LECTURES ON NEUROLOGY.

The British Medical Association, Victorian Branch, in conjunction with the University of Melbourne has organized an excellent series of lectures on clinical neurology. The course has been well attended, the lectures were delivered by Dr. J. H. Anderson, Dr. R. R. Stawell, and Dr. Frank Andrew.

MEDICAL STUDENTS AT THE UNIVERSITY OF MELBOURNE.

The number of entries of first-year students of medicine for the current academic year shows a diminution, and for the first time since the origin of the war approximates more nearly to what may be regarded as normal. The following figures, which are not without interest, show the number of first-year students for the respective years:

1913	98	1917	163	1920	202
1914	116	1918	192	1921	151
1915	99	1919	209	1922	110
1916	127				

During the whole of this period no attempt has been made by the University Council to restrict the numbers to those for which the University has accommodation, nor has there been any increase in the fees. The results to the University have been somewhat disastrous, as the teachers have been overburdened, and the true function of a university—the advancement of knowledge by research—has become an impossibility.

Leave of absence for twelve months from last May has been granted to Dr. W. A. Osborne, Professor of Physiology, in order to visit America and Great Britain.

THE International Congress of Comparative Pathology, which was to have taken place at Rome in September, has been postponed till next spring.

THE eleventh Italian Congress of Stomatology will be held in Rome on October 1st under the presidency of Professor Piergili, when the following subjects will be discussed: Lesions of the masticatory apparatus in relation to the laws of industrial accidents, introduced by Professor Beretta; modern progress in facial orthopaedics, introduced by Professor D'Aliso; the question of extractions in dento-facial orthopaedics, introduced by Professor Boggio; anaesthesia in dentistry, introduced by Dr. Cavina; modern views in the application of movable and immovable dental prosthetics, by Dr. B. de Vecchis.

Correspondence.

BONE-GRAFTING IN TUBERCULOUS SPINAL CARIES.

SIR.—Mr. Roth, in his letter published in the JOURNAL on August 12th, writes that certain statements made by Sir Henry Gray on the subject of bone-grafting for spinal caries are open to serious criticism, and he proceeds, with emphasis to condemn the operation without reservation. Sir Henry Gray based his observations on a series of twenty-eight cases, and it so happened that when his paper appeared a communication of mine (made to the Royal Academy of Medicine in Ireland some months ago), dealing with twenty-seven similar cases, was in the hands of the printers. My deductions and results correspond in a large measure with those recorded by Sir Henry Gray, and I expressed an opinion in favour of operation in selected cases.

Before analysing Mr. Roth's "serious criticism," I can make my own position clear by quoting Royal Whitman (1919). He expresses admirably what I believe is the position of most surgeons when called upon to decide between the operative and non-operative treatment of spinal caries.

"One may conclude, therefore," he says, "that operative treatment, although of the greatest value in selected cases, particularly in the adolescent or adult class, is not to be undertaken as a routine measure in the treatment of Pott's disease, but that it is distinctly supplementary to conservative treatment."

And again: "Operations of this character are more likely to be successful in the operative sense in the adolescent or adult class than in early childhood."

I have read Mr. Roth's letter paragraph by paragraph.

1. He objects to the statement that fixation is essential to success, and adds that physiological rest is prevented by absolute fixation. He contends that the argument of easy operative fixation as against difficult mechanical fixation therefore does not arise. I wonder how many experienced orthopaedic surgeons will agree with Mr. Roth on the question of absolute fixation and physiological rest.

2. Sir Henry Gray points out that the behaviour of an abscess in cases of spinal caries treated by operation is uncertain. Mr. Roth reads into this statement the meaning (abscess, he says, occurs in 48 per cent.) that nearly half the cases derive no advantage from operation as compared with non-operative treatment. "On Sir Henry's own showing," he says, "even if he is right, nearly half the cases would not be cured any quicker by operative methods." There was nothing in Sir Henry's paper which conveyed this meaning to me. I have had four cases of spinal abscess, treated exhaustively without success, get rapidly well after bone-grafting the diseased spinal segment. I believe it was the absolute fixation which brought about so happy a result.

3. Sir Henry Gray quotes authorities and statistics which appear to show the higher mortality following the conservative form of treatment. Mr. Roth could have perhaps helped us in this matter, for accurate statistics with regard to mortality in this disease, for obvious reasons, are difficult to obtain. Whitman, according to Gray, said (in 1901), "At least 20 per cent. of all patients die during the progress of the disease." "Could he have not quoted from a more up-to-date book," says Mr. Roth, "as, for example, Rendle Short's *Index of Prognosis*, 1918, second edition, where we are told that we may take it that the mortality is about 5 to 10 per cent.?" I have before me Royal Whitman's book (1919), kindly sent by the author, and the 20 per cent. statement is repeated. If Mr. Roth desires still more recent literature the Mayo Clinic's 1921 volume has just arrived from the publishers. He will find in this a study of 166 patients treated by bone-grafting for spinal caries, and a statement from Henderson that the results of operative are better than the results of non-operative treatment. Henderson concludes his paper by saying, "I shall continue to advise operation in adults."

4. Mr. Roth says, "He [Sir H. Gray] surely must know that it is usually the onset of deformity which first draws attention to the presence of disease." Surely Mr. Roth does not intend this statement to be taken literally. It is common knowledge that the disease is, and should be, recognized in most cases long before deformity occurs. He quotes Rollier in support of the statement that in all active cases the deformity can be entirely reduced except in the cervical and lower lumbar regions, and pleads, "Can we then advise patients to have an operation to cure (*sic*) them, and thereby

force them to remain humpbacked for life, when another form of treatment can make them *perfectly* straight?" (the italics are mine). How many surgeons can promise all kyphotic patients complete restoration when the disease is active? "This a consummation devoutly to be wished," but I will quote Whitman once again: "When the deformity is present," he says; "it can be remedied only in part, and it may be difficult even to check its progress." At operation considerable reduction of deformity can often be accomplished, but I take it that most surgeons obtain all correction possible by postural and other methods before introducing the graft in cases selected for operative treatment.

5. Mr. Roth concludes his letter with a reference to the operation of craniectomy, which was tried and abandoned as a treatment for microcephalic idiots—"their [the surgeons'] eyes were opened and they were able to perceive the error of their ways." "Is it too much to hope," he asks, "that this history may soon repeat itself?" There is another side to this picture and it teaches a second lesson. In the past every step forward in surgery and medicine was obstructed by professional die-hards—as, for example, the introduction of antiseptics and anaesthetics. It is the same to-day: the die-hards are content if surgery and medicine remain in the well-worn rut.—I am, etc.,

Dublin, August 13th.

W. I. DE C. WHEELER.

Sir,—May I enter a protest, if such be necessary, against the letter by Mr. Bernard Roth in the JOURNAL of August 12th? The question of the correct treatment of spinal caries is not yet settled, and I do not think that Mr. Roth's letter contributes in any way towards its settlement. While attempting to throw doubt on the value of the statements made by Sir Henry Gray, he asks us to accept without any question the statistics given by Dr. Rollier and to be guided by them. Is it not possible that there may be other optimists than Sir Henry Gray, and that Dr. Rollier may be one of them? Whatever may be the value of Dr. Rollier's figures, it is limited by the fact that it is impossible for us in this country to treat cases of spinal caries under the same ideal conditions as he does.

I have treated several cases without fixation of any kind, and found the method to be of value only when the disease had become quiescent, and when the weather conditions, particularly as regards the amount of sunshine, were more favourable than they usually are.

I have had several cases of abscess in which fixation, exposure to the sun, and aspiration (repeated when necessary) failed to give a good result, and in which the abscess was rapidly absorbed after a bone graft had been inserted by Albee's method. I regret that I have not the exact figure at hand, but I have operated on over twenty cases and there has not been any mortality. Operation should certainly be done before deformity has occurred. Usually the deformity is slight when the patients are first seen, and it can by a few weeks' postural treatment be modified to such an extent as not to be noticeable. With regard to cases where advanced deformity has taken place, when one reflects on what has actually happened to the body tissue of two or three vertebrae it is difficult to accept Mr. Roth's statement that "Rollier has shown that in all active cases the deformity can be reduced except in the cervical and lower lumbar regions."

Mr. Roth wouders "if anything more is needed to open your readers' eyes to the real state of affairs" than Sir Henry Gray's account of four cases in which the result of his treatment has been unsatisfactory. I should think that the obvious answer to this is that we need an equally candid account of a series of cases treated, under similar conditions, by non-operative methods.

We are not likely to arrive at a method which will cure every case of spinal caries, but I think we have in spino-plasty a method of treatment which, when used with judgement and discrimination, is of very great value.—I am, etc.,

ALEX. MITCHELL,

Surgeon, Royal Aberdeen Hospital for Sick Children.

Aberdeen, Aug. 13th.

THE TEACHING OF PSYCHOTHERAPY.

Sir,—I feel I am to be congratulated in that my letter has brought forth replies from two such authorities as Dr. Potts and Dr. Crichton Miller. I am sorry that Dr. Potts does not look upon psychotherapy as a science. That it is also an art, I agree; but if I did not believe that it were founded on sound scientific principles I, for one, would have nothing

more to do with it. What I do object to is the attitude of mind which would make it a mystery as well. I believe that a certain amount of team work is possible in psychotherapy, as in other branches of medicine. That the relations between a patient and his analyst must be of a peculiarly intimate and confidential kind goes without saying, but this should not be a bar to collective investigation in the way I suggested by men who approach the subject in a strictly scientific spirit. In the course of the analysis of their dreams they would have to learn to overcome their own repressions and to stand mentally and morally naked before each other; but once a man has progressed far enough to admit of the possibility of unsavoury complexes within himself the scientific frame of mind would carry him through. In such an investigation carried out by normally well-balanced individuals the question of transference would not arise. After all, I do not believe that every dream of the normally adapted individual shows necessarily either sexuality or antisocial tendencies. There are many egoistic impulses in us all which do not come under either category, and to my mind the problems of dreaming can be better studied in the normal than in the pathological.

I was very interested in Dr. Crichton Miller's account of the method of teaching employed at the Tavistock clinic. It is evidently on very sound lines. If such recognized centres could be allowed to grant diplomas the possession of such would be a valuable guide to the general practitioner in the selection of a specialist, although due provision should be made for those older men who, in the face of far more opposition than exists to-day, upheld the banner of psychotherapy in the years before the war. In conclusion, I am rejoiced to read that at the recent meeting of the British Medical Association in Glasgow a resolution was passed by the Section of Neurology and Psychological Medicine advocating the addition of psychology to the student's curriculum. This marks a big advance in the right direction.—I am, etc.,

Birmingham, Aug. 12th.

R. MACDONALD LADELL.

THE CONTROL OF BIRTH CONTROL.

Sir,—The accumulated evidence is now overwhelming, both statistically and from many recorded individual experiences, that the present practice of voluntary birth control is entirely harmful in its dysgenic results. The regularity and care required for its successful employment renders it utterly ineffective among the worst classes, while the most highly civilized are the most easily tempted to substitute personal convenience for possible children. It is therefore high time for the scientific control of birth control, and some such definite system should be inaugurated, as, for example, the following:

1. A central committee should be appointed of medical men of approved status who should control the whole subject of birth control, and whose decisions should be referred to them.
2. Criminals should be compulsory sterilized.
3. In cases unable to maintain themselves or their children the woman should be temporarily sterilized by compulsion for varying periods—for example, by the insertion of the spring wish-bone pessary.
4. The open sale of contraceptive books and mechanical devices should be prohibited in public places, such as general stores, etc., so that no unnecessary temptation should be put before parents to sacrifice their potential children to personal convenience or luxury.
5. Indiscriminate propaganda by irresponsible lay persons, journalistic or otherwise, should be similarly dealt with for similar reasons, as is now being done in France since the war.
6. Cases of normal people specially desiring contraceptives for urgent medical or economic reasons should be referred through their family doctor or welfare centre to the above central committee, who should supply limited quantities for limited periods to necessary cases, thus establishing control analogous with that of morphine and cocaine.
7. Where both parents were absolutely determined to employ contraceptives without justification, then these might be supplied in return for a stiff graduated tax, which should be applied for the benefit of larger families of the same class.
8. Stiffening of parental instinct should be bestimulated, especially in the desirable classes—for example, professional—to cope with the attack of modern city conditions plus contraceptive inducement.
9. The survival rate, on the analogy of the production of a lethal virus with a selective action.
10. If a protective tradition is well seen in the world, with this matter, which constitutes a racial asset favouring their survival over surrounding groups less developed in consciousness.

The above is only a framework requiring much fuller elaboration and definition before becoming workable, but

something of the sort is urgently necessary in national interests.

The recent annual baby week, with its infant welfare schemes, and indeed all the organization for reduction of infantile mortality, are somewhat farcical if we remain inactive with regard to the poor survival rate of the professional and similar classes. It seems the height of inconsistency and incongruity that the birth prevention of more than half of the possible children of the better classes should excite less repression than the abortion of prostitutes and imbeciles, which is a criminal offence.—I am, etc.,

London, N.W.

STERILIZATION OF MENTAL DEFECTIVES.

SIR,—With reference to Dr. Arnott Dickson's letter in the JOURNAL of August 12th (p. 285), I would refer him to a brochure entitled *American Sterilization Laws*, by Bleecker van Wagenen, issued by the Eugenics Education Society, London, and another entitled *Eugenical Sterilization in the United States*, by Harry S. Laughlin (1920), issued by the American Social Hygiene Association, 370, Seventh Avenue, New York. Later information will shortly be available in a book by Harold Cox, editor of the *Edinburgh Review*, which is now in process of publication. By the courtesy of Mr. Harold Cox I am able to quote the following particulars:

State.	Date Enacted.	Permission of Relatives.	Total No. of Operations.
Indiana ...	1927	Not required	1,200
Washington ...	1929	Not required	1
California ...	1909	Not required	2,558
Connecticut ...	1923	Not required	27
Iowa ...	1911	Not required	49
New York ...	1912	Not required	42
North Dakota ...	1913	Not required	23
Michigan ...	1913	Not required	1
Kansas ...	1913	Not required	54
Wisconsin ...	1913	Not required	56
Nebraska ...	1915	Required	155
Oregon ...	1917	Required	127
Total ...			4,313

* Repealed 1920.

† Declared unconstitutional 1918.

London, W., Aug. 12th.

NORMAN HAIRE.

HAEMOLYTIC AND WATER FEVERS.

SIR,—In your review of our article dealing with haemolytic and water fevers (ERRATA, April 1st, 1922, p. 52), you state that we conclude that no reliable evidence of pure haemolytic fever exists, and that, in consequence, the fever in paroxysmal haemoglobinuria must be due to some other cause.

This does not give our conclusion correctly. What we state is that the fever is due to some *unknown* cause. The evidence brought forward by Yamakami of being able to produce fever in rabbits by inducing haemolysis simply was shown to be unreliable. We are not prepared to say that haemolysis is not concerned in the production of the fever, but if this is the case no evidence has yet been adduced to prove it. No experiments have been done yet, so far as we are aware, to ascertain the effect of distilled water haemolysis in animals suffering from chronic infections. We believe it possible that the haemolysis in paroxysmal haemoglobinuria in the presence of an infection might induce fever, and many of these patients are known to be syphilitic. What we stated before and now restate is that no reliable evidence of pure haemolytic fever exists and that the cause of the fever in paroxysmal haemoglobinuria is still unknown.

It has already been shown by Hort and Penfold that a quantity of bacteria, unable in itself to produce fever in the rabbit, will produce a well-marked fever if it be administered intravenously in distilled water, or if the animal be sensitized by the previous injection of distilled water. This, however, cannot be looked upon as a haemolytic fever simply, for the bacterial poison must have been introduced simultaneously with or about the same time as the water. Moreover, it has not yet been proved that the sensitizing effect of the water is due to the haemolysis.—We are, etc.,

W. J. PENFOLD,
D. G. ROBERTSON.

Commonwealth Serum Laboratories,
Royal Park, Victoria, June 23rd.

PRACTICAL PSYCHO-ANALYSIS.

SIR,—In your issue of July 15th there appears a review of my book *Practical Psycho-Analysis*. In this review the mode of criticism adopted by the writer is much to be deplored and deprecated. As, however, he is not the only sinner in this respect, perhaps you will generously grant me the privilege of some of your valuable space in order to put him and other sinners right in this very important matter—to lead them along the path of righteousness to the goal of reformation.

The main functions of criticism are, or should be, to illuminate and to inform. If it is necessary to destroy, the destructive process should be followed by a reconstruction. Purely destructive criticism is worthless. A critic, too, should avoid careless writing, cultivate a clear and literary style of composition and be alive to the responsibilities of the high duties of his office.

The following extract from the review in question, affords an excellent example of careless writing and of purely destructive criticism at the same time—

"Some of his explanations are confusing and may fail to convey any meaning. This is particularly the case in his treatment of *libido*, *affect*, and *desire*, much of which leaves the reader puzzled and far from clear in his mind as to the distinctive meanings of these terms."

Naturally, if the reader is puzzled he cannot be "clear in his mind." The criticism too is purely destructive and therefore worthless. To make it of any value, the writer should substantiate his statements by quoting from my book examples of confusing explanations, and he could then further add to the value of his criticism by substituting clear explanations for those that he finds confusing. He does none of those things, and therefore his criticism is worthless.

But the delinquencies of this gentleman who has done me the honour to review my little work, do not end here. He attributes to me expressions which I did not use—for instance, the expression "repressed experiences." For the sake of clarity it will be better to quote this passage in full. The reviewer writes:

"It is thus misleading to describe the 'preconscious' as the seat of repressed experiences, which can only be brought into consciousness indirectly, and to state that the mental processes included therein are concerned with the primary instincts and are largely in the nature of sexual wishes."

I never use or never have used the phrase "repressed experiences" as it is likely to give rise to ambiguity; for an experience may be an occurrence, an actual physical happening, in which case it cannot even be conceived of as being repressed, or it may be a mental process or a group of mental processes, for example, a phantasy—in either of which cases it may be repressed if it is intolerable to the personality. Also if it happens to be a mental process or a group of mental processes of the nature of an unpermitted sexual wish, it very often is repressed into the preconscious and as it is sexual it necessarily is concerned with the primary instincts.

If I have unnoticed other observations of your reviewer, I feel sure you will understand that I do this out of regard for your space. It is for the same reason I compress my remarks. Almost every proposition he advances is of the nature of an unsupported opinion. Criticisms of this type are not worth the paper they are written on—they have no scientific or any other value and if you will excuse me, Sir, for saying so, they have no proper place in the columns of the BRITISH MEDICAL JOURNAL.—I am, etc.,

Shotley Bridge, Aug. 7th.

H. SOMERVILLE.

"DOCTORS IN COUNCIL."

SIR,—I am glad that Dr. Peter Macdonald has drawn attention (August 12th, p. 284) to the supposed value of honorary hospital appointments. At the present time especially it is constantly being brought forward by laymen as an argument against paying the staff. There is no doubt that the advantages, repute, and profit said to attach to these appointments are much exaggerated; it is apparently always forgotten that what value there is is entirely potential and depends on the personality of the holder. This appointment is indeed his opportunity; he might use his chance for unremunerative scientific research, or for professional work on behalf of the patients in the hospital which may lead to lucrative practice. These appointments may be, as the *Manchester Guardian* says, "The entrance gates to most lucrative fields of private practice," but not everyone who passes through these gates

reaps this particular harvest; in any case if one does gather a crop that he sells at a good profit in the open market it is only by his skill and his industry that he is enabled to do so.

In the case of the smaller hospitals, so-called cottage hospitals, there are no gates open only to a select few, and leading to these "lucrative fields of practice"; every practitioner working there cultivates a crop for his own consumption—there is no outside market for it. In other words, a member of the staff of a cottage hospital attends there mostly his own private patients, the work he does there brings him little, if any, reputation outside the district in which he practises and no lucrative work in the way of consultations or operations. The work he does there is an advantage to him in that it makes him a more efficient practitioner, but this is equally an advantage to all his patients, and if both he and his patients do benefit the benefit is strictly proportioned to the industry and skill with which the doctor has pursued his hospital work.

There can be no doubt that even in the central hospitals these appointments should in the interests of all be open to as many as possible, and if the holder of one fails to make proper use of his opportunity there should be some means of replacing him by another who may do better.—I am, etc.,

Bradford-on-Avon, Aug. 14th.

CHAS. E. S. FLEMING.

MARRIED MEDICAL WOMEN.

SIR,—Allow me to back up the remarks of Dr. Marion Mackenzie in your issue of May 20th, received rather late, as I am not in England. As a fellow Scotswoman, I admire her for speaking her mind. As myself a doctor of twenty-five years and a mother of seventeen years' standing, I cordially agree with her remarks on the futility as well as the injustice of debarring a medical woman from certain posts because of her being married. The affairs of the married are only fully understood by the married. If the married treat the single, at least they have themselves been single once. Medical men usually find marriage benefit their practice. Simpson, for example, had to marry in order to obtain the chair of obstetrics at Edinburgh. This is not only a question of propriety—it is a feeling that the man who most wearily realises what marriage and maternity mean to a woman is the man who unites the feelings of husband and father to the knowledge of the physician. Women have not this knowledge either till they marry. Medical women are all the better for having in their ranks, as they have had from the first, a certain number of married women. When all is said and done, married people frequently do not care to enter into many medical details with bachelors and spinsters.

There are signs that the much tried mother is rebelling against the constant dictation and inquisition into all her doings carried on by spinsters and sometimes by bachelors. I saw a book once on a stall entitled *A Book for Mothers by a Mother*. There is no doubt that patients frequently believe more in a doctor who is a parent—and faith counts for something still. The Chinese, indeed, regard medicine as an old man's and preferably as an old woman's trade. If "knowledge through suffering entereth" there is something to be said for this view. The multiplication of books for junior practitioners on sex surely proves the same. The money for maternity and child welfare clinics is found by townsfolk who, as a rule, are married; I fail to see that posts in charge of wives and children should be necessarily used as mere charities for childless women. There are many people who think that all such clinics, and also venereal hospitals, should be officered solely or chiefly by married people who are also parents. Many clinicians have sounded a warning against the mere laboratory worker. From the economic point of view, the wives of to-day complain, "First the spinsters do our men out of a job. Then they forbid us wives and mothers to earn. Then they turn round and grab such children as we dare to have, and tyrannize over them and us. Are we to be mere machines for bearing children?" It is the home we are fighting for. Single professional people can earn a living—so can husband and wife, if they part and abandon the children. The mother, and the father in his measure, who have watched children develop, with eyes made wise by love and also sharpened by professional experience, know more than all the bachelors and spinsters put together, with the rare exception of "born" mothers and a very few "born" fathers, such as Froebel, Barnardo, Ozanam, and Vincent de Paul. The modern system of passing the child on from mother to child's nurse, from unmarried woman doctor or health visitor to school medical officer, usually unmarried

also, and nurse, and the kindergarten teacher to the preparatory and so to the public school, leaves the parent and family doctor and the priest (if any) the only persons who know the individual from birth to adult life; and of these the parent alone as a rule knows the family history. In the medical parent these opportunities are united. Is the public as a whole to lose the advantage of their experiences, or anyhow when that parent is a mother?

If the objection to married women is their possible state of health, may I inquire if Hunter was immediately made to resign on account of his aneurysm? The public in general benefits so much from the devotion of doctors to duty in spite of ill health that it seems a little absurd to press this point. Woman is usually penalized all round. The Post Office Insurance people, for example, and some others, go on making a woman pay at the rate of labour risks long after the climacteric. The yellow, black, and brown races do not penalize marriage. Are we sure enough of our ground to justify all or any of us in so much petty regulation as goes on to-day? If the plea for dismissal is the woman's health, let her husband and herself settle this—anyhow, in the case of a medical woman. If she cannot take care of her health, who can? And is the public always so considerate for doctors' health? Can temporary leave not be given?—I am, etc.,

Durban.

MARGARET LAMONT.

THE ANTIVIVISECTION SOCIETY: AN APOLOGY.

SIR,—In the May, 1922, number of a journal, *The Animals' Defender and Zoophilist*, issued by the Antivivisection Society, there appeared an article, written by the Hon. Mr. Stephen Celeridge, in which it was suggested that the annual parliamentary return, made by the Home Office, of experiments on living animals performed by licensees under the Act 39 and 40 Vict. c. 77 (known under the short title of "The Cruelty to Animals Act, 1876") during 1920 represented "a deliberate *suggestio falsi*." The article proceeded with the suggestion that, with the connivance of the Home Office, certain licensees under the Act had made false returns of experiments performed by them on living animals during the year 1920. As the result of certain action taken by the solicitors representing one of the licensees referred to in the Hon. Mr. Stephen Celeridge's article, the following retraction of, and apology for, the untrue and libellous suggestions made therein was published in the July and August numbers of *The Animals' Defender and Zoophilist*:

APOLOGY TO MR. A. G. FOULERTON, F.R.C.S.

In the issue of this journal for last May, on pages 7 and 8, appeared an article entitled, "Is it only innocent credulity?"

The article contained statements which have been understood as accusing Mr. Foulerton of having knowingly signed false returns in returns made by him to the Home Office (in regard to experiments made on living animals under licences granted to him pursuant to statute), and of having committed criminal offences.

Our suggestions to that effect were made without any foundation, and we are satisfied that there is absolutely no justification for any accusation of the kind.

We apologize to Mr. Foulerton for having made the statements complained of, and sincerely regret the pain and annoyance which he has thereby suffered.

—I am, etc.,

London, W.C., Aug. 8th.

ALEX. G. R. FOULERTON.

SIMPLE GOITRE.

SIR,—Gastro-intestinal infection as a causative factor in simple goitre is, on the authority of Lieut.-Colonel McCarrison (*BRITISH MEDICAL JOURNAL*, April 22nd, 1922), an admitted fact. His example of the European school in India, which became entirely free from goitre on being provided with a bacteriologically pure water supply, is sufficiently convincing.

In rural districts in this country it is not always possible, from economic and other reasons, to provide a pure water supply. The use of thymol and beta-naphthol has proved to be capable of causing the disappearance of recent goitres in young subjects (*The Thyroid Gland*, McCarrison, p. 91). The administration of these, however, requires constant supervision, which is somewhat difficult in a scattered rural population.

In a district where endemic goitre is very prevalent and the water supply indifferent I have used in a number of cases during the past twelve months keratin-coated capsules of oxygenated hydrocarbons of high boiling point of the tar-acid series from which the phenols and cresols have been distilled. The resultant antiseptic is of high germicidal efficiency (Rideal-Walker coefficient 30) and of low relative

toxicity to carbolic acid (1 to 90). I have found that in the majority of early cases treatment extending over a period of from four to six weeks causes a complete disappearance of the swelling. The capsules may be given for prolonged periods without giving rise to any ill effects.

Boiling all drinking water is not sufficient to eliminate the possibility of soil infection in an infected area.

In cases of long standing the administration of small doses of iodine to supply the iodine needs of the body and to relieve the strain on the thyroid hastens the reduction of the goitre.

—I am, etc., R. HENSLEIGH WALTER, M.B.
Stoke-under-Ham, Somerset, Aug. 12th.

TOBACCO SMOKE AND CANCER.

SIR,—In your issue of August 5th Colonel Duer quotes a New York surgeon as saying that he had never met with a case of malignant disease of the lips, tongue, mouth, or throat in a non-smoker. In common, doubtless, with all laryngologists, I have had numerous cases in patients who had never used tobacco. I have recorded six cases of intrinsic cancer of the larynx in females who had been non-smokers all their lives. In each case the diagnosis was confirmed by the microscope. They did not chew betel-nut or indulge in any similar habit, and they were either teetotalers or extremely temperate drinkers.—I am, etc.,

London, W., Aug. 15th.

ST CLAIR THOMSON.

NATIONAL ASSOCIATION OF OPTICIANS.

SIR,—On July 10th I received a communication from the National Association of Opticians inviting me to examine their candidates in the anatomy and the abnormal conditions of the eye. I have found reason to suspect that this was probably part of an insidious attempt on behalf of this society to secure recognition for their members and to obtain for them a status similar to that which is possessed by midwives.

As a practising ophthalmic surgeon I have therefore thought it advisable to raise this matter in your columns lest others should be approached with the same object. We do not want this new class of practitioner. Recognition by the State, together with certificates of competence from members of our profession, would still further confuse the lay mind in its power to distinguish between an ophthalmic surgeon and the optician.—I am, etc.,

Manchester, Aug. 3rd.

CYRIL JACOBS.

* * For a craft to seek to ascertain or secure the efficiency of its craftsmen is not reprehensible. Two points are, however, essential: (1) that the craft shall have a well-defined and accepted sphere; (2) that those who practise it shall not pretend to be other than they are. In both these respects the movement initiated by the National Association of Opticians needs to be carefully watched, and it is desirable that further information with regard thereto should be supplied by our readers.

Obituary.

MARRIOTT LOGAN ROWAN, M.D.,

Medical Superintendent of Derby County Asylum.

His many friends will read with regret of the death of Dr. Marriott Logan Rowan, which occurred with tragic suddenness at St. Anne's-on-Sea on August 6th. He had been in poor health for some time, and had left Derby only two days before his death. Dr. Rowan was born at Carrickfergus, co. Antrim, in 1871, and was educated at Queen's College, Belfast. He graduated B.A. (with honours), and M.B., B.Ch. at the Royal University of Ireland in 1900; and in 1903 he graduated M.D., and a year later he became assistant medical officer at Derby County Asylum. He was appointed medical superintendent in 1915, a post he filled with much distinction till the time of his death. The many improvements that followed his appointment bear witness to his deep interest in the staff and patients, and a touching tribute to his memory was the spontaneous gift of a beautiful wreath from the patients of each side of the institution. Possessing a generous and kindly nature, to all who were privileged to know him his death comes as a personal loss. Much sympathy has been extended to his widow and two little children.

We regret to announce the death of Dr. RICHARD CHARLES MASON POOLEY, which occurred at his residence, 20, 1st Road, Regent's Park, on July 30th. Dr. Pooley was born in Ireland in 1848, and received his medical education in Dublin. He took the diplomas of L.R.C.S.I. and L.R.C.P.I. in 1871, the M.R.C.P.I. in 1900. In his earlier days Dr. Pooley had a busy and successful career as a surgeon in Rochdale, and in 1891 the appointment of honorary surgeon to Rochdale Infirmary. He was the author of a number of contributions to this journal on medical and surgical subjects. He was a justice of the peace, a Fellow of the Royal Society of Medicine, and a member of the British Medical Association, as well as a representative of the London Panel Committee, in the work of which he took an active interest. At one time he was a keen Territorial officer, and retired from the R.A.M.C. with the rank of major; he held the Volunteer Decoration. His kindly nature and his professional ability made him a beloved and respected by all who came in contact with him.

Dr. ANDREW MURRAY NEETHLING, who died recently in Pretoria, was born in Cape Colony, and educated at Edinburgh University, where he graduated M.B. and C.M. about 1880, and subsequently took the degree of M.D. After studying the Continent, he returned to South Africa, where he was to practice successively at Barberton and at Lydenburg until the outbreak of the South African war, throughout which he served. After the war he sat in the Cape Colony Parliament as member for Beaufort West. In 1914 he served under General Botha as the rank of colonel in the campaign which reduced German South-West Africa. After the capture of the capital, Windhoek, he was appointed chief medical officer of the conquered territory. He married a daughter of the late Mr. Duncan Wilkie Paterson, S.S.C., of Edinburgh, and leaves a widow and three children. His two elder sons served with him in the campaign in S.W. Africa, where the elder was killed in action at the pass of Kakamas.

Dr. FREDERICK HAYCRAFT BERRY of Watford died on July 29th, aged 66. He was the eldest son of the late Dr. H. Berry, of Anwell Street, London, and received his medical education at Guy's Hospital Medical School. He took the diploma of M.R.C.S. in 1878 and graduated M.B. Lond. with honours in 1880 and M.D. in 1886. After serving as house physician and resident obstetrician at Guy's Hospital he joined the late Dr. A. T. Brett in practice at Watford in 1888. He took great interest in the establishment of the Watford District Hospital, of which he was for many years honorary medical officer; on his retirement from that post was appointed honorary consulting surgeon. He was president of the Watford and West Herts Medical Society, a member of the West Hertfordshire Division of the British Medical Association, and a representative for Watford on the Hertford Panel Committee. Among his medical appointments were those of medical officer to the London Orphan School, the Post Office, and the London and North-Western Railway. He was a governor of the Grammar School and a trustee under the Morrison Charity. During the war his eldest son, Lieutenant P. H. Berry, R.A.M.C., lost his life in South Africa in a heroic attempt to save a private soldier from drowning.

We regret to announce the death, on July 30th, of Dr. CHARLES MITCHELL MACQUIBBAN, J.P., who was the oldest medical practitioner in Aberdeen, having been born in that city eighty-nine years ago. He was educated at Aberdeen University, graduated M.B. in 1861, and M.D. and C.M. in 1863; he took the diploma of L.R.C.S. Edin. in 1863. During the Crimean war he volunteered for service in the army, but as hostilities were approaching a termination his services were not required. In 1861 Dr. MacQuibban began a long military career by becoming attached as assistant surgeon to the 7th Volunteer Battery of the Aberdeen Artillery; he was later attached to the Gordon Highlanders (Militia), and finally retired with the rank of surgeon lieutenant-colonel in 1899. In 1913 he was appointed senior medical officer of the National Reserve. He was a very well known figure in the community, and enjoyed the genuine affection and respect of all classes. A few months ago he fell from a tramcar, and from the effects of this accident he never recovered. He is survived by two daughters.

WE regret to record the death, suddenly, on August 8th, of Dr. WILLIAM ROBERT WILLIAMS, of Machynlloth, Montgomeryshire. Dr. Williams was educated at Edinburgh, and took the diplomas of L.R.C.P. and L.R.C.S. Edin. in 1888. He was one of the best-known medical practitioners in his district, and held many public offices. He was a justice of the peace, honorary surgeon to the local cottage hospital, assistant medical inspector of schools for the county, and an ex-chairman of the local urban district council. He held a commission as Captain R.A.M.C.(T.), and was attached to the 7th Royal Welsh Fusiliers. He was a member of the British Medical Association. His funeral was attended by a firing party of the 7th Royal Welsh Fusiliers and by a very large assembly of people. He leaves a widow, two sons, and two daughters, with whom much sympathy is expressed.

The Serbires.

THE King of Egypt has conferred the Order of the Nile (fourth class) upon Captains Eric D. M. Heriot-Hill and Stanley Arnott, R.A.M.C., in recognition of services rendered during the operations against Aliab Dinkas in the Mongalla Province.

DEATHS IN THE SERVICES.

Surgeon Commander James Garfit Wallis, R.N., died recently at Plymouth. He was educated at the London Hospital, where he was Buxton Scholar, and took the M.R.C.S. and L.R.C.P. Lond. in 1897, and the M.D. Lond. in 1899. After filling the posts of house-physician and clinical assistant in the aural, ophthalmic, and skin out-patient departments at the London Hospital, and assistant house-surgeon at Poplar Hospital, he entered the navy as surgeon, taking the prize for tropical diseases at Haslar. He attained the rank of surgeon commander on February 25th, 1914, and in April, 1920, was appointed health officer of the port at Devonport.

Lieut.-Colonel John Joseph Falvey, R.A.M.C. (retired), died on May 21st, aged 70. He was born at Tralee, educated at the Ledwith School of Medicine, Dublin, and took the L.R.C.S.I. and L.A.H. in 1876, and the F.R.C.S.I. in 1886. He entered the army as surgeon on August 10th, 1878, and became lieutenant-colonel after twenty years' service, and retired in 1900. He had a long list of war service: the Boer war of 1881 in the Transvaal, including the defence of Lydenburg, mentioned in dispatches; Egyptian war of 1882, medal and Khedive's bronze star; Sudan, 1884-85; Nile campaign, with the heavy camel corps, action of Atkhien, and engagements during return to Korti, two clasps; and South African war, 1899-1900, Queen's medal with clasp.

Lieut.-Colonel James Young, Bengal Medical Service (retired), died at Bedford on July 13th, aged 76. He was the son of John Young, of Bathgate, West Lothian, and was educated at Edinburgh, where he graduated M.B. and C.M. in 1868. He entered the I.M.S. as assistant surgeon on March 30th, 1872; he became surgeon lieutenant-colonel after twenty years' service, and brigade surgeon lieutenant-colonel in 1897; after officiating for some time in the administrative rank as A.M.O. of the Calcutta district he retired, with an extra pension, on March 31st, 1902. He served in the Burma war of 1885-86, taking part in the occupation of Mandalay, and received the frontier medal with a clasp.

Colonel John Donald Alexander, C.B.E., D.S.O., Army Medical Service (retired), of Bideford, died in Queen Alexandra's Military Hospital, Millbank, on July 9th, aged 55. He was born at Callan, in Ireland, on April 11th, 1867, the eldest son of the late Very Rev. John Alexander, Dean of Ferns, and was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., and B.A.O. in 1889. He entered the R.A.M.C. as surgeon lieutenant on January 30th, 1892, attained the acting rank of colonel on March 23rd, 1916, while holding the post of A.D.M.S. of a Division, was confirmed in that rank on December 26th, 1917; placed on temporary half-pay on account of ill health on November 26th, 1919, and retired on February 3rd, 1920. He served on the North-West Frontier of India in the Tirah campaign of 1897-98, taking part in the capture of the Sampahla and Ashanga passes, the reconnaissance of the Saran San, operations round Dwatol, against the Khanikhel Chamkanis, and in the Bazar Valley, and in the action at Shinakman, receiving the frontier medal with two clasps. In the South African war of 1899 to 1902 he served in the relief of Ladysmith, action at Colenso, operations on Tuge's Heights, action at Pieter's Hill, the relief of Mafeking, and the action at Frederikstadt, was mentioned in dispatches, and received the Queen's medal with five clasps, and the King's medal with two clasps. His services in the recent war of 1914-18 were mentioned in dispatches in the *London Gazette* of January 4th and May 29th, 1917; he received the D.S.O. on June 3rd, 1917, and the C.B.E. on June 3rd, 1919.

Captain Ernest Neville Keys-Wells, R.A.M.C.(T.F.), died in London on July 30th. He was the fourth son of the late Rev. William Keys-Wells, of Clifton Rectory, Penrith, and was educated at Edinburgh, where he graduated M.B. and C.M. in 1888. He served as a civil surgeon in the South African war, in the operations in Natal, receiving the Queen's medal with a clasp. In the late war he held a commission as captain R.A.M.C.(T.F.) in the 3rd London General Hospital from March 19th, 1915.

Medical News.

SIR WM. THORBURN, K.B.E., C.B., C.M.G., F.R.S., has been appointed a member of the Advisory Committee under the Administration of the Cruelty to Animals Act.

THE King of Egypt has conferred the Order of the Nile (third class) upon the following in recognition of valuable services rendered: Dr. Harold Benjamin Day, professor at the School of Medicine, Cairo; Mrs. Cornelius B. S. Elgood, M.B., senior lady medical officer, Egyptian Ministry of Education; and Dr. Alexander A. W. P. Morrison, medical officer, Egyptian State Railways.

THE King has approved the retention of the title of Honourable by Dr. Charles Ferdinand Marks and Dr. William Frederick Taylor, who have served continuously for a period of not less than ten years as members of the Legislative Council of the State of Queensland.

THE following members of the British Medical Association have been appointed Knights of Grace of the Order of St. John of Jerusalem: Major J. R. Williams, Penmaenmawr (late High Sheriff of Carnarvonshire), and Surgeon Lieut.-Colonel J. D. Lloyd, Chirk.

SPECIAL courses in diseases of the heart and gynaecology will be held at Franzenbad (Czecho-Slovakia) from the 21st to the 24th of September by Drs. A. Ghon, R. Jaksch, R. Schmidt, and G. A. Wagner of Pragno, J. Halban, F. Hirschmann, J. Pal, and H. Thalmer of Vienna, H. E. Hering of Kiel, R. T. von Jaschke of Giessen, H. Kehrner of Dresden, O. Minkowski of Breslau, Seitz of Frankfurt, Volhard of Halle, G. Winter of Königsberg, and K. Zörkendorfer of Prague.

AMONG the recipients of civil pensions is Dr. Francis Warner, who in consideration of his circumstances receives £100 in recognition of services rendered in his investigation into the mental and physical condition of defective children.

THE Scottish schools have been celebrating the close of the term by speech days. At the ceremony at Ballachulish Dr. Lachlan Grant not only gave an address, but supplied the prizes, which the education authority, for reasons of economy, had ceased to give. At the Morrison Academy, Crieff, the medal was presented to the dux by Dr. Gairdner, who, in an address, mentioned that he himself had received the medal in 1852, and that he had since been for fifty-five years medical officer for Crieff.

THE annual dinner of past and present students of University College Hospital will be held at the Hotel Cecil on Friday, October 6th, 7.30 for 8. The chair will be taken by Sir Dawson Williams, C.B.E., F.R.C.P., Editor of the BRITISH MEDICAL JOURNAL. The secretaries are Dr. A. M. H. Gray and Mr. Gwynne Williams, 30, New Cavendish Street, W.

THREE blind students (two civilians and one ex-soldier), trained at the Massage School of the National Institute for the Blind, have passed the recent massage and remedial gymnastics examinations of the Society of Massage and Medical Gymnastics. Another civilian student, for whom the National Institute paid fees and expenses at a Liverpool massage school, has also passed the massage examination. Two blind women masseuses have passed in remedial gymnastics.

DURING last June 481 deaths from plague occurred in Java; in June, 1921, the number of deaths from this cause was 520.

ROENTGENOLOGY has recently been made a compulsory subject for the medical curriculum in Rumania.

AT Wimbledon police court, on August 8th, James Allport, described as a pathologist, of Cheltenham, was charged with unlawfully and wilfully pretending to be a registered medical practitioner. A full report appears in the *Wimbledon Boro' News* for August 11th. Mr. G. D. Roberts, instructed by Messrs. Hempson, presented on behalf of the Medical Defence Union; there was not, he said, anything to prevent a man practising medicine, whether he was registered or not, if he could find people to entrust themselves to his tender mercies, but the law said it was an offence to pretend to be a registered medical practitioner if you were not. The accused was engaged through an agency as a locum tenens by Dr. Sweetnam of Wimbledon Park, who believed him to be a registered practitioner, and he attended patients and signed medical certificates. The accused said that he told the agents that he was not qualified for general work, and also that he had tried to get bacteriological or x-ray work. During the war, he said, he had been an acting medical officer at an infirmary. After evidence had been given of certain other charges against him Allport was fined £20, with the alternative of three months' imprisonment, on the charge of pretending to be a registered medical practitioner, and sentenced to three months' imprisonment on other charges.

Letters, Notes, and Answers.

owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

Correspondents who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Persons desiring reprints of their articles published in the British Medical Journal are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the British Medical Association and British Medical Journal is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the British Medical Journal, *Attilage*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 15, South "Bacillus, Dublin; telephone, 4737.
- 6, Inthland Square, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

"N. E." asks for information as to the present condition of Carlsbad, and the cost of a course of treatment there.

"M.D." asks for information about the Portuguese Riviera as a winter resort for a patient subject to bronchitis. He desires information, among other points, on the cost of living and the sanitary and social conditions.

WARTS OF THE SCALP.

DR. JOHN S. CLARKE (Weobley) writes in reply to "X. Y. Z.": I can vouch for the efficacy of freezing by carbolic acid snow. I have recently had the treatment myself at the hands of a colleague. The effect is most gratifying. Rather deep freezing was employed. Practically no discomfort was occasioned. Very little hair had to be snipped away. After ten days the hair on the area treated was showing signs of growth.

ALUMINIUM COOKING VESSELS.

A CORRESPONDENT asks whether any danger can arise from the use of aluminium cooking utensils. He wishes to know whether acid or fruit juices may form poisonous salts or milk be contaminated.

"*.* Aluminium is the best metal next to gold or platinum for culinary utensils. It is better than silver, for silver is more quickly corroded by table salt than is aluminium by the acids of fruit. Moreover, the injury to be apprehended from the results of the corrosion suffered, even if the corrosion were considerable, is insignificant in the case of aluminium, since the product of corrosion would consist only of that which is a common constituent of almost every ordinary food as well as of drinking water.

INCOME TAX.

"R. S. V. P." is being pressed by the income tax inspector to employ an accountant to prepare statements of receipts and expenses and of assets and liabilities.

"*.* That course may be usual among traders holding substantial stocks and business assets of various kinds, but is not usual among medical practitioners. It is not clear why this inspector should ask for statements of assets, etc.; if the return has been correctly computed year by year on the basis of the total gross cash receipts, less specified expenses under the usual heads, it seems that the "assets" figures will serve no useful purpose.

"D. W." has been asked by the inspector of taxes to state the amount of his outstanding book debts for the adjustment of his cash basis return.

"*.* The authorities at Somerset House have officially acquiesced in the "cash basis" method of computation, subject to any particular cases in which that basis would for some special reason be an unfair index of the income accruing from the practice. We advise our correspondent to remind this inspector that the cash basis has official sanction and to ask why it should be refused in his case.

"O. H." is employed as an assistant and earns sundry fees in addition to his salary. Can he still claim the three year average?

"*.* If the fees are paid by the practitioner whom he assists the answer is, No; if otherwise he can average the fees but must accept assessment on the current year's basis as regards the salary.

"R. C. P." renewed his car in 1921 and was allowed the whole the cost. He has since renewed it again, but the authority claim to exclude one-third of the cost because to that extent the car is used for pleasure, though it was primarily bought for professional purposes.

"*.* The expense claimable is the amount necessitated for professional use. It would seem that the private use lasts the date when renewal becomes necessary, and that it is the fore right that some adjustment should be made in calculating the renewal allowance for tax purposes; whether one-third is a reasonable proportion we cannot, of course, say.

"FINANCE" "has set up in practice" for the first time and inquires as to allowances for (1) outlay on instruments, medicines, books; (2) surgery, rent, and expenses; (3) hire of motor car for place of owning a car; (4) remuneration of locum tenens for holiday purposes.

"*.* (1) Not allowable—only expense of renewals can be claimed; the original stock represents capital outlay; (2) allowable in far as actually incurred and within reason; (3) allowable; (4) allowable.

LETTERS, NOTES, ETC.

DIABETES IN THE TROPICS.

LIEUT.-COLONEL E. E. WATERS, I.M.S. (Calcutta), writes: In the kindly review of June 24th, 1922, on my book on diabetes, it is asked whether the book is on sale in England. Will you allow me to state that the publishers have arranged for its sale in London by Messrs. H. K. Lewis, and in Edinburgh by Messrs. Blythe?

MEASLES WITH MULTIPLE TUBERCULOUS MANIFESTATIONS.

DR. N. WALSH (Swindon, Wilts) writes: F. W., a girl, aged 8, who first seen, was suffering from coryza, slight cough, and pyrexia (103°); the pulse was rapid. The chest was carefully examined but only slight signs of catarrhal bronchitis were found. A there was at the time great prevalence of measles, it was thought that the patient might be suffering from that disease. She was put to bed and placed under expectant treatment. A few days later she vomited—mainly a green fluid—but not very violently and on only one occasion. The temperature was 101° and the pulse 94. There were signs of conjunctivitis, photophobia was present, and pain was complained of in the region of "the back of the eyes." The slight cough disappeared, and although the chest was carefully watched, no signs of bronchitis or pneumonia were ever found. The following day the rash appeared. It was typical of measles, and was very abundant. It disappeared on the seventh day, but the temperature was still raised: it advanced to 104.5° and kept at that level for seven days. Then the cervical glands became enlarged and formed projections at both sides of the neck, about 4 in. by 3 in. Difficulty in deglutition and rapid emaciation ensued. The pulse became soft, rapid, and irregular, and in spite of stimulants the cardiac action showed signs of failing, which gradually became more and more evident. There was also extreme tenderness of all the limbs, the child moaning when they were merely touched.

Another feature was oedema of the right arm from shoulder to elbow. The abdomen, which had been normal, began to show signs of distension which rapidly increased; a little fluid was then made out. The surface veins were well marked, the stools became loose, and the whole condition of the abdomen became very suggestive of tuberculous peritonitis. The child now showed some retraction of the neck, dilated and unequal pupils, and a meningeal cry. Kernig's sign appeared; the temperature fell to 100.4°, and the patient died on the eighteenth day.

This case is interesting from the multiplicity of the lesions, and from their rapid appearance. It is remarkable that at no stage was there any serious chest trouble.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 25, 26, 28, 29, and 32 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 30 and 31.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 96.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under
Each additional line
Whole standard column (three columns to page)
Half standard column
Half page
Whole page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

114. Toxic Effects of Helminthiasis and the Endocrine Glands.

P. SIMONIN (*Rev. méd. de l'Est*, May 15th, 1922, p. 314) enumerates the cardinal symptoms of helminthiasis, and states that recent discoveries regarding "foreign proteins" have considerably expanded our knowledge of the toxins resulting from the presence of intestinal worms. These include every poisonous substance or group of substances which may give rise to symptoms in the patient, whether resulting from the secretions of the parasite, from its metabolic activity, or from disorders of the patient's metabolism produced by the presence of entozoa. The author claims that clinical observations regarding the interference of these toxins with the functions of the endocrine glands have been fully confirmed by recent experiments. He considers that the well-known fact that patients infested by the entozoa often lose weight rapidly, in spite of a good appetite and an apparently unimpaired digestion, is due to interference with the process of oxidation of carbohydrates and hydrocarbons, which has been noted by several observers in the course of ankylostomiasis, and that this interference arises from diminution of ferment activity which, in its turn, is the result of "glandular insufficiency" directly traceable to cellular toxic degeneration of the liver, pancreas, and suprarenals. On the other hand, the urine often contains excess of nitrogen bodies and of phosphates, showing that abnormal tissue destruction is in progress. In some cases the patient becomes cachectic from the double process of imperfect assimilation and excessive tissue destruction. In children and young people growth and development are seriously interfered with; several authors have described the physical and mental degeneration of children in Tunisia suffering from ankylostomiasis. Siccardi has termed this "ankylostomal infantilism," as in these patients the mental and physical characteristics of infancy persist beyond the age of puberty. Similar observations have been recorded by the American Commission in Porto Rico. He considers that the numerous records of cases of amenorrhoea, dysmenorrhoea, metrorrhagia, and abortion attributed by various authors to helminthiasis show that these parasites have a distinctly toxic action on the ovaries, numerous cases having been reported by Tridonau in which abortion has taken place after complete destruction of the ovaries. After quoting examples from the author describes in detail the changes in the endocrine glands—the suprarenals, thyroid, and ovary—after experimental injection of fluids obtained from hydatid cysts, from ascari, etc., and a number of plates illustrate the description. The author concludes that further observations in clinical medicine and experimental pathology will bring about a more general recognition of the part played by helminthiasis in the production of general malnutrition and systemic disturbances.

115. Neuro-recurrences following Salvarsan Treatment.

E. L. ZIMMERMANN (*Arch. Derm. and Syph.*, June, 1922, p. 723), from a series of 37 cases treated with arsphenamin (salvarsan) types: a diffuse meningo-encephalitis; fluid is abnormal; and focal lesions chiefly involving the second, seventh, and eighth cranial nerves, without diffuse cerebral changes. The initial course of treatment in early syphilis consisted of six doses of 0.3 to 0.4 gram each of arsphenamin at weekly intervals, followed by a course of mercury by inunction. Clinically three groups of neuro-recurrences were noted: (1) acute syphilitic meningitis, with or without focal lesions; (2) slight meningitis symptoms of headache and focal lesions; (3) a focal lesion without any general symptoms of meningitis. Occurring weeks or months after the interruption of antisiphilitic treatment such neuro-recurrences are the result of resumed activity of temporarily suppressed organisms in a host whose resistance has not developed owing to therapeutic interference, and occasionally a secondary syphilide will develop simultaneously with the appearance of a neuro-recurrence, the temporary suppression of infection by arsphenamin being followed by a flaring up of neuro-syphilis when the treatment is suspended. Meningitic symptoms subside rapidly if intensive antisiphilitic treatment is instituted early, one patient, who had been comatose for forty-eight hours, recovering under

spinal drainage, with intravenous administration of neo-arsphenamin and mercurial inunctions. Intravenous therapy usually suffices when neuro-recurrences develop six or eight weeks after arsphenamin treatment, but when they occur during or a few days after a course satisfactory results can only be obtained by intraspinal therapy. Mercury has a marked protective action against neuro-recurrences, it being immaterial whether it is employed simultaneously with, or immediately following, a course of arsphenamin.

116. Effect of War Diet on Graves's Disease.

H. CURSCHMANN (*Klinische Wochenschrift*, June 24th, 1922, p. 1296) records that during the period of underfeeding in the recent war the number of cases of Graves's disease in his practice (hospital and private) in Rostock greatly diminished; also severe cases were less numerous. Other physicians in Rostock and Mecklenburg had similar experiences. Since the middle of 1919 (when the food, as regards meat and fat, rapidly improved) the number of cases of Graves's disease has rapidly and considerably increased. Similar improvement was produced by underfeeding in the war period as regards diabetes, gout, cholelithiasis, some forms of constipation, and obesity. During this period of underfeeding the author noted an increase in the number of cases of myxoedema, and an increase of the symptoms in those already suffering. He quotes the experiences of twelve other physicians and surgeons in Germany who noted a definite diminution of the number of cases of Graves's disease, and especially of the severe cases, during the years of underfeeding. The cause of this diminution is carefully discussed, and the author concludes that underfeeding has a depressing influence on the functions of the thyroid gland and that abundant feeding has a stimulating influence on the gland. Also he considers it is probable that not only meat but also fat and excessive feeding generally are able to lead to an increase of the function of the thyroid gland, and thus, in Graves's disease, probably to an injurious increase of the activity of the gland as regards internal secretion. These observations support the views of Blum as to the value of a diet free from meat in Graves's disease.

117. The Relation between Bronchial Asthma and Pulmonary Tuberculosis.

E. BUFALINI (*Il Policlinico*, Sez. Prat., May 29th, p. 703) remarks that the views on the relations between bronchial asthma and pulmonary tuberculosis have undergone considerable changes within the last thirty years. The old doctrine of an antagonism between asthma and tuberculosis rested on the belief that asthma was a manifestation of arthritism which was regarded as incompatible with tuberculous infection. Landouzy was the first to contest this doctrine, and not only denied the existence of this antagonism but declared that bronchial asthma was an expression of larval tuberculosis. Investigations on the relations between bronchial asthma and tuberculosis were conducted by Bufalini on 22 patients with bronchial asthma, 10 of whom were men and 12 women. In 15 there had been a history of respiratory affections such as pneumonia, bronchitis, or pleurisy, preceding the onset of the asthma. Although only one showed active tuberculous lesions of the lung, 19 reacted positively to tuberculin by the cuti-, intradermo-, or subcutaneous method. X-ray examination showed tuberculous lesions in the lungs, especially at the apex or hilus glands, in 8 cases. Bufalini comes to the following conclusions: (1) There is no real antagonism between bronchial asthma and tuberculosis. (2) The existence of true bronchial asthma of tuberculous origin is not proved, nor does anything support the theory of the anaphylactic asthma as maintained by Landouzy. (3) On the other hand, the presence of latent tuberculous lesions either in the pulmonary parenchyma or in the lymphatic glands is frequent. In such cases tuberculosis may favour the outbreak of asthma in predisposed persons just like non-specific respiratory affections.

118. Dried Milk.

LEARY (*Boston Med. and Surg. Journ.*, May 4th, 1922) points out that it is the fluid nature of milk that renders it a perishable food, and adds considerably to the expense of its delivery to the consumer. By the two standard processes of drying milk its constituents are altered by heating, but these alterations do not seriously affect its nutritive value, and reconstituted dried milk corresponds closely in chemical composition with boiled and sterilized milk. In the roll process the milk adheres for a few seconds to the surfaces of

rolls heated to from 110° to 140° C., while by the spray process the milk is atomized under pressure into a chamber where it meets whirling currents of warm air, the temperature being lower but the process longer than in the former method. The spray process is more destructive of the antiscorbutic properties than the roll process, but in practice no diet should depend upon milk, either raw or dried, for its antiscorbutic element, the substance being given in addition to the diet by the administration of orange juice, etc. Full-cream milk powder will keep in tins at least three months, and skimmed milk powder at least a year. By the use of dried milk, milk-borne epidemics are eliminated, since the drying process destroys the organisms originating in the milk as drawn, or renders the multiplication of those contaminating it through handling improbable, and economically much of the expense of transit is saved. By the development of present-day apparatus it should become possible for milk producers to dry their own milk at the source, which would cheapen it considerably to the consumer, a result which would also follow its more universal use. It must be borne in mind that dried milk when reconstituted is as good a culture medium as fresh milk, and consequently such reconstituted milk should only be prepared as it is required, in order to prevent contamination.

119. Palliative Treatment of Hay Fever.

DIETSCH (*Deut. med. Woch.*, May 19th, 1922) has found in his own case and in that of many of his patients that an attack of hay fever often culminates in violent sneezing followed by considerable relief. He has therefore attempted to abort these attacks by inducing early sneezing. His insufflates a mixture containing 3 parts of pure eucalyptol, 40 of oil of eucalyptus, and 60 of liquid paraffin. This acts as a mild transitory irritant which is sufficient to bring on an attack of sneezing. While the insufflation is proceeding the patient's head should be bent forward, and when the insufflation is completed the head should be flexed backwards and the eyes fixed on some bright object overhead. Sneezing then sets in, and the insufflations should be repeated till they can no longer provoke sneezing. It is well at the completion of this treatment to wash out the mouth with a gargle. The insufflations leave a pleasantly cool feeling in the nose. The author admits that the composition of the prescription is not perfect and that one with a better taste would be preferable.

SURGERY.

120. Deep X-ray Therapy.

PONZIO (*Rif. Med.*, May 3rd, 1922, p. 433) says we ought to accept with caution the hopeful views of the effect of deep therapy in malignant disease. That it is a considerable advance in treatment, that it does improve certain cases and holds out prospects of better results when more is known, he feels sure; but that is a long way from speaking of it as a systematic cure of cancer. It is not merely a question of mathematically calculating the exact dosage for each class of growth, writing as it were an electro-physical prescription, but one ought to estimate all the clinical aspects of the case as well, and adapt the method to the disease, and not the disease to the method.

121. Radium in Exophthalmic Goitre.

W. I. TERRY (*Journ. Amer. Med. Assoc.*, July 1st, 1922, p. 1), from a total of 33 cases, advocates the use of radium emanations in the treatment of exophthalmic goitre. The skin over the thyroid is anaesthetized at the sites selected with a small cotton sponge saturated with ethyl chloride, and the minute capillary tubes containing the emanation are inserted by means of a hollow needle with plunger. Usually from six to eight tubes, containing a total of from 4 to 10 millicuries, according to the size of the goitre and intensity of the symptoms, are inserted into the upper, middle, and lower thirds of each lobe through one skin puncture on each side. On examining the changes produced each tube is seen to be the centre of a small white area, mostly fibrin, with a narrow zone beyond of degenerating thyroid and increased connective tissue, and beyond this compact thyroid tissue with undifferentiated cells, the alveoli being lined by enboidal or low columnar epithelium and containing little or no colloid. The final results observed in 16 of the 33 cases treated showed that the emanations are of value in preparing serious cases for resection, and in 2 there was an apparent cure by radium alone. While the treatment might be of value in the colloid and simple hypertrophic types, it is contraindicated in adenomatous goitres on account of the danger of producing atrophy of the gland proper and consequent hypothyroidism. Investigations showed that the frequency of haemorrhages

within adenomas is due to the weak walls of the intracapsular veins, which are deficient in adventitia, musculature, elastic tissue, so that any abnormal intravenous pressure such as that produced by coughing, might easily cause rupture of a vein within the capsule.

122. The Value of Early Operation in Acute Haemorrhage from Gastric and Duodenal Ulcers.

H. FINSTERER (*Klinische Wochenschrift*, June 17th, 1922, p. 1253) advocates early operation, within twenty-four to forty-eight hours, without awaiting the result of medical treatment, in cases of acute haemorrhage from gastric and duodenal ulcers. Against early operation it is urged (1) that death is exceedingly rare when such cases are treated medically, and (2) that the results of surgical treatment are worse than those of medical treatment. But Finsterer points out that death from these haemorrhages is not so rare as usually believed (in ten years in Vienna hospitals 992 were found *post mortem* and 150 deaths from erosion of large vessels in the ulcer); also he asserts the results of medical treatment are not better than those of surgical treatment but to the opposite (statistics given). The longer the haemorrhage continues the greater the anaemia and the risks of bad results afterwards; and hence the value of early operation. Early operation the patient escapes the danger of fatal haemorrhage from erosion of blood vessels, especially ulcers extending to adjacent organs. By early operation the risk of perforation is avoided. Finsterer considers that when the diagnosis should not be difficult; but that in doubtful cases exploratory operation (under novocain anaesthesia) is justifiable. The results in early operation are dependent upon certain arrest of the haemorrhage; and this is best obtained by resection of the ulcer and ligation of eroded vessels (7 cases of ulcer of the stomach and 6 of ulcer of the duodenum all cured by resection of the ulcer). The author employs novocain anaesthesia in all cases. His mortality in these early operations was 5.5 per cent.

123. The Kondoleon Operation for Elephantiasis.

F. P. HERFF (*Surg., Gynec., and Obstet.*, June, 1922, p. 75) reminds us that elephantiasis is pathologically due to a obstruction of the lymphatic vessels of the part, resulting in hyperplasia of the skin and tissues, which microscopically are thickened, waxy, and indurated. The operation devised by Kondoleon of Greece cannot be considered as a cure in this condition, but it is the best operation so far introduced tending to make lymphatic obstruction of limbs bearable and controllable. Before operating the following should be observed: a negative Wassermann, patient's general health carefully considered, and every means of reducing the size of the limb must be tried, such as rest, elevation, massage, and elastic bandage. Such precautionary measures reduce the chance of infection and make the affected area more pliant. The principle of the operation is the establishment of a connexion between the superficial and deep lymphatics—the latter generally being involved. This is done by breaking the fascial wall between the muscles and subcutaneous tissues by removing wedges from the inner and outer aspect of the entire length of the affected limb. Each wedge comprises skin, fat, and deep fascia. It is an advantage to break the incision opposite the joints. Drainage is usually employed, as it allows general reduction of the limb and lymph to escape. After operation the limb is firmly bandaged and elevated and the patient not allowed to walk for a month and then only with a bandage on. Some sort of support must be worn, and light massage given from time to time. A complete cure cannot be obtained, but recurrence can be held in check. The author reports three cases treated by this method.

124. Surgical Treatment of Gastric Crises.

GIORDANO (*Rif. Med.*, June 5th, 1922, p. 530) reports the case of a woman, aged 36, suffering from tabetic gastric crises (Argyll Robertson pupils, no knee-jerks, ataxia, paraesthesia, etc.). Treated medically by strychnine, valerian, radiotherapy, suspension, neo-salvarsan, silver nitrate, and paracanthidina canterization with no benefit, the stomach was explored under local anaesthesia, the vagus nerve cut, and the fibres of the sympathetic separated. Posterior gastro-enterostomy was also done to avoid gastric stasis. The stitches were removed on the eighth day, which proved too soon, as shortly after the stomach and colon protruded. On the tenth day the patient suffered from incontinence of urine. Meanwhile the gastric crises had ceased, but two months later reappeared and have continued at varied intervals since, but are much less troublesome, and fourteen months after operation the patient, although still weak as a tabetic, reported herself much better as regards the gastric attacks and having put on weight.

125 Butyn as a Cocaine Substitute.

W. M. BEAUMONT (*Brit. Journ. Ophthalm.*, July, 1922, p. 316) advocates the use of butyn as an ideal substitute for cocaine in ophthalmic practice, it being free from the disadvantages of mydriasis and desiccation of the cornea. Combined with eserine in the treatment of glaucoma it minimizes the twitching and discomfort which may be experienced from eserine alone. From his own experience he confirms the findings of the committee appointed by the American Medical Association that it has a more powerful action, and therefore can be used in less quantity than cocaine; that its action is more rapid and prolonged and less toxic; that it is non-irritant, and does not affect the pupils or the accommodation; and that its efficiency is unimpaired by boiling. Satisfactory results followed its use in 2 per cent. solution in operations for the extraction of cataract and iridectomy, and in 1 per cent. solution it produces anaesthesia without causing conjunctival infection when used for the removal of foreign bodies in the cornea and conjunctiva, and its use as a lotion to relieve pain in herpes of the head and eye, and in detachment of the retina, is advocated. It used in combination with other drugs its incompatibility with chlorides must be borne in mind. Having no attraction for the drug taker, its possibilities for reducing the necessity for the manufacture and sale of cocaine are obvious.

126. Appendicitis the Cause of General Chronic Debility.

A. MUELLER (*Deut. med. Woch.*, June 16th, 1922, p. 798) develops the theory, on the basis of about 600 operations on the appendix, that appendicitis is only a link in a comparatively long chain of events which profoundly affects the general health. An attack of diarrhoea in infancy is followed by constipation and chronic colitis; or an attack of dysentery or typhoid fever in childhood is followed by constipation and chronic colitis. The appendix becomes involved, and constipation becomes aggravated by a sedentary life and neglect of regular defaecation. This state of affairs may last for decades, and the dramatic exacerbation which leads to an operation for appendicitis is but a short page in a long chapter. There are many children who do not thrive but who show no definite symptoms apart from headache and a tender point over the appendix. Appendectomy in these cases acts like a charm. In women the uterine appendages are often involved by extension of the inflammation from the appendix, and the differential diagnosis between appendicitis and colpitis is the less important, as in a large number of cases they represent one and the same disease, for which there is but one satisfactory treatment—operation.

OBSTETRICS AND GYNAECOLOGY.

127. Radium Treatment of Cancer of the Cervix.

M. RICHARD (*Paris Méd.*, June 17th, 1922, p. 511) describes radium treatment of cancer of the cervix uteri as carried out at the Pasteur Institute. With regard to early malignant disease, limited to the cervix, with no clinically demonstrable affection of the parametria, surgical intervention is indubitably indicated if microscopical examination of an excised piece of the growth shows the presence of aberrant inclusions derived from the stratum corneum; in other cases the admissibility of radium treatment as an alternative to operation, although challenged, has not been disproved. Concerning combination of surgical with radium treatment of these early cases it is said that post-operative radium applications should be abandoned; they are made at a moment when the cancerous cells are most radio-resistant and when an application must necessarily be remote from the parametria and the pelvic wall, and near to the intestine, which at all costs should be respected. In the writer's experience pre-operative radium applications, made with proper technical precautions three weeks before performance of hysterectomy, have been attended with fortunate results, and have not increased by production of dense scar tissue the operative difficulties. For more advanced but still operable cases (for example, those with involvement of the inner portion of the parametria) a combination of x-ray, radium, and surgical treatment, employed in the order named, is recommended; in the case of other than baso-cellular epitheliomata the x-rays are omitted. The radiations are conducted within as short a period as possible and operation is performed three weeks later. Another line of treatment employed for this group of cases consists in hysterectomy together with introduction of radio-active tubes, contained in a sound of which one end is left in the region of the bifurcation of the iliac vessels and the other protrudes in the vagina (preoperative x-ray or radium applications are sometimes made in addition); the pain and persistent discharge which often ensue are a drawback to this technique, which

was prescribed by Dominici and Desjardins. With regard to inoperable cases, invasion of the bladder or rectum constitutes a contraindication to all active treatment. In the absence of such complications, x-ray or radium treatment is given according to the degree of radio-sensibility indicated by microscopical examination of an excised piece of growth. Radium treatment may be given *per vias naturales*, by the Dominici-Desjardins method, or by introduction, after laparotomy, of rubber drains, containing radium salts or emanation in Regaud's needles, into the body and cervix of the uterus and into the broad ligaments (Regaud-Richard technique). The third method is attended by less shock than the second. Other contraindications to local treatment are given by extreme cachexia of the patient, by extensive infiltration of the vaginal vault, and by involvement of the lumbar glands, as found at operation and indicated by persistent severe lumbar pain.

128. Diffuse Adenomyoma of the Uterus.

SCHWARZ and MCNALLEY (*Amer. Journ. of Obstet. and Gynecol.*, May, 1922, p. 457) discuss the etiological factors concerned in the production of diffuse uterine adenomyoma on the basis of a study of 23 early and 26 well-advanced cases in which the uterus was submitted to microscopic examination. They agree with Cullen and with Frankl that inflammation plays an inconspicuous part, and is frequently entirely absent. In the present series, diffuse adenomyoma was accompanied practically always by other uterine lesions; hyperplasia of the endometrium, subinvolution, or myomata were present (alone or combined with one another) in 26, 34, and 21 respectively of the 49 cases. Hyperplasia of the myometrium was noticed in most cases, but varied in degree from case to case; it was characterized by hyperplasia and hypertrophy of muscular and connective tissue elements; and by absence of signs either of degeneration or round-cell infiltration. The genesis of diffuse uterine adenomyoma is explained by the writers chiefly on mechanical grounds. Subinvolution favours invasion of glands from the mucosa, with reaction by the myometrium resulting in some instances in hypertrophy; the absence of myometrial hypertrophy in some cases of subinvolution is ascribed to the somewhat atrophic condition of the endometrium. In cases associated with endometrial hyperplasia, this lesion is to be regarded as primary; a resulting work hypertrophy of the myometrium gives it a coarse structure, and allows mucosal extensions to penetrate between the widened interstices. In cases associated with myomata in the absence of endometrial hyperplasia or of subinvolution a similar work hypertrophy consequent on the presence of discrete nodules of new formation predisposes to penetration of the endometrium. Clinically 31 of these 49 cases were associated with menorrhagia, the incidence of which appeared to be dependent to a large extent on the existence of endometrial hyperplasia.

129. Physiological Ascites in the Female.

NOVAK (*Zentralbl. f. Gynäk.*, May 27th, 1922) has remarked the finding of a moderate amount of free fluid in the pelvis at operation cases—for example, those of uterine malpositions or myoma—in which there is no suspicion of inflammation or irritation of the pelvic peritoneum such as, proceeding from recent adnexial disease or torsion, might account for an exudation of peritoneal fluid. A similar finding has not been recorded in the male. Of 33 recent operation cases, 21 showed, in the absence of acute or subacute inflammation or peritoneal irritation, ascites; it was found that the sole distinction between these cases and those in which free fluid was absent consisted in the presence of a recently ruptured ovarian follicle or a fresh corpus luteum. The suggestion is put forward that the ripe follicle and the early corpus luteum lead to the production of a peritoneal irritation and exudation; the latter may have the physiological function of favouring the transit of the ovum. Free fluid was absent in cases of corpus luteum cyst, and also when the corpus luteum by reason of ovarian disease did not impinge on the surface of the ovary.

130. Retention of Urine in the Puerperium

P. ZACHARIAE (*Hospitalstidende*, May 3rd, 1922, p. 293) observes that, according to Knapp, the first spontaneous evacuation of urine after labour occurs in about 50 per cent. of all cases as late as twelve hours *post partum*, and that intervals of twenty-four to thirty-six hours are not uncommon, although the last interval must be indicative of pathological conditions. Various simple devices, such as warming the bed-pan, hot compresses on the abdomen, and letting the patient sit up and swing her legs over the edge of the bed, are often successful, but if they are not, there are the alternatives of exerting light pressure with one hand on the bladder or passing a catheter. The author prefers the former, pointing out that it is not always easy to find the

pening of the urethra after it has been bruised and stretched by labour. The use of the catheter also requires great cleanliness. But pressure on the bladder is not devoid of risk; even in the hands of a skilled nurse, and in this connexion the author records the case of a primipara, aged 29, who suffered from pyelitis during pregnancy. Expression of the bladder in the puerperium was followed by intraperitoneal rupture of the bladder. The symptoms were those of acute intestinal obstruction rather than those of ruptured bladder; there was little shock, no vesical tenderness, and the urine drawn from the bladder after the accident was not blood-stained. Although laparotomy was not performed till twenty-four hours after the accident, and the rent in the bladder was large, complete recovery was effected.

131. Hyperemesis Gravidarum.

ACCORDING TO VERRUCOLI (*Annali di Ostetricia e Ginecologia*, March 31st, 1922), cases of hyperemesis gravidarum at the Pisa Clinic numbered 17 in twenty-six years; multiparae were affected more frequently than primiparae. In 2 instances the vomiting was attributed to grave organic disease, and proved fatal. In the remaining 15 cases of true pernicious vomiting of pregnancy uterine displacement was absent save in one instance, renal function was normal, and cure was attained by simple administration of anodynes. It is concluded that hyperemesis gravidarum is very rarely due to pregnancy toxæmia, and is always almost an entirely functional condition.

132. Radiotherapy in Cancer of the Uterus.

SPEAKING at a meeting, at Frankfurt a.M. on April 23rd, of the German Central Committee for the Study and Combating of Cancer, D. SEITZ (*Deut. med. Woch.*, May 26th, 1922, p. 716) discussed the results which he and Wintz had obtained at Erlangen with radiotherapy. Some cases of cancer of the uterus had been treated with a combination of radium and x rays, and others with the x rays alone. Although every case, including the most unfavourable cases, was counted, and more than two years had passed, 56 per cent. in the former class, and 53 per cent. in the latter class, were still alive and well. Cases treated with radium plus x rays have now stood the test of a five-year observation period, and of 58 cases of carcinoma of the cervix 12 were still alive five years after treatment. A permanent cure could be claimed in 50 per cent. of the cases of sarcoma of the uterus, and of 132 cases of genital and extragenital sarcoma 59, or 45 per cent., were still alive two to five years after treatment.

PATHOLOGY.

Dental Caries.

133. MCINTOSH, JAMES, and LAZARUS-BARLOW (*Brit. Journ. of Exper. Path.*, June, 1922, p. 138) claim to have isolated two types of bacilli which are the infective agents in dental caries, and for which they propose the names of *B. acidophilus odontolyticus* 1 and 2. When grown in glucose broth these organisms produce great acidity, and the final P_H value of the broth after several weeks' growth may be as acid as 2.75. Teeth left in contact with pure cultures of these organisms show first of all a loss of transparency of the enamel, which becomes opaque—the first sign of dental caries—and sections from such teeth show that the organisms have penetrated the dentinal tubules for a considerable distance. Control teeth kept in cultures of *Streptococcus salivarius* and *B. coli* showed no such changes. Having penetrated through the enamel these *acidophilus* bacilli may proceed to liquefy the dentine, for it can be shown that when completely deprived of carbohydrates the organisms isolated can exert a liquefying action on the collagen matrix of the dentine. In natural caries, however, it is probable that this liquefaction of the dentine is carried out by secondary bacterial invaders, the chief function of *B. acidophilus odontolyticus* being to produce sufficient acid to decalcify teeth and to initiate dental caries. Two types of bacilli are described. Type 1 is a long, thin bacillus with a marked tendency to parallelism or palisade formation in dried films; type 2 is a shorter bacillus growing in chains. Both are Gram-positive and non-motile. They show a finely granular scanty growth on agar, a turbidity in broth, and do not liquefy gelatine. The sugar reactions are somewhat variable, but most strains produce acid but no gas in glucose and lactose.

134. Cytological Researches on Glioma of the Retina.

To decide as to the real nature of the so-called glioma of the retina J. MAWAS (*Bull. Assoc. française pour l'étude du Cancer*, May, 1922, p. 209) has undertaken a detailed study of several cases. Immediately after enucleation the eye was fixed either in 10 per cent. formalin, or in Bouin's picro-formalin acetic mixture, or in Zenker's fluid. Various methods for staining for special tissues were employed. Examination of the

tumour after fixation in formalin showed that on gentle shaking a number of fine filaments became visible, which were however, of neuroglial nature, but resulted from the gelation of necrosed areas of the tumour. From microscopic observation he describes the growth as consisting of type of tissue which appears in two forms: (1) as active proliferating groups of deeply stained cells lying in relation to the blood vessels—these he calls the germ zones; and (2) as pale areas of avascular and necrotic appearance—these are centres of degeneration. Close study of former type of cell shows it to possess a limiting membrane from which little protuberances of cytoplasm project, giving it a similarity to the embryonic visual cell. From this conclusion that the neoplasm is not a glioma, but should be regarded as a malignant tumour of epithelial origin, consisting of retinal cells whose development is atypical and does not proceed to complete maturity.

135. Cholera.

MASKI (*Ann. de l'Institut Pasteur*, May, 1922, pp. 399-415) in an article on the mechanism of infection in cholera, describes the effect produced by injecting the vibrios by various routes. After intraperitoneal inoculation the organisms pass immediately into the blood and thence to the intestine; ten be after inoculation cultures from the peritoneum, blood, and bile are negative, whilst the vibrios are abundant in the small intestine, where they remain for two or three days. When the organisms are injected subcutaneously a small abscess forms, from which the vibrios are transported to the intestines, where they make their appearance in about 48 hours. Injected intravenously the organisms rapidly disappear from the blood as before, to reappear after a brief interval in the intestines. When vibrios are administered to the mouth rabbits do not develop any agglutinins or protective antibodies unless the organisms are given at previous sensitization with bile according to Besredka's method. Such sensitization leads to agglutinins, which are of a higher titre than those of dead vibrios than after living vibrios. It appears to be any relationship between immunity and the presence of agglutinins in the serum, and the only animals which appeared to possess protective substances were rabbits which had been previously sensitized and had ingested living cultures. This the author attributes to the existence of local intestinal immunity due to recovery from a mild attack of the disease.

136. Sedimentation of Erythrocytes in Pelvic Disease.

LINZENMEIER (*Zentralbl. f. Gynäk.*, April 8th, 1922), from observation of the rate of sedimentation of the red blood cells in 230 patients suffering from adnexal disease, pelvic peritonitis, or complicated extrauterine gestation, comes to the following conclusions: In differential diagnosis between recently ruptured ectopic gestation on the one hand, and acute adnexal or other pelvic inflammations on the other, slow sedimentation rate points with great probability to ectopic pregnancy. Observation of this rate is of great assistance in fixing the time at which operative intervention may with propriety be undertaken for the inflammatory adnexal affections; if the time of sedimentation be under one hour it is possible that virulent micro-organisms are still present in the inflammatory mass, and operation should be deferred. On the other hand, no local infection need be feared if the sedimentation time is over two hours. A sedimentation time of less than thirty minutes points to a acute inflammatory process, with the single exception that in cases of ruptured tubal pregnancy with profuse intra-abdominal hæmorrhage there is also a greatly increased sedimentation velocity. According to Linzenmeier measurements of the erythrocyte sedimentation rate afford a much more delicate index of persistence of bacterial infection than is offered by the most careful observations of the body temperature.

Visceral Nitritoid Crises.

137. H. GUGEROT (*Paris Méd.*, May 13th, 1922, p. 393) states that since nitritoid crises following injections of salvarsan were first described by Millan there has been too great a tendency to suppose that the cephalic region only is affected, as shown by congestion of the face and oedema of the bucco-pharynx and larynx. Millan, however, in addition to the ordinary form had described several localized forms, including hæmorrhagic and asthmatic varieties. Gugerot now reports a case of a utero-placental nitritoid crisis giving rise to abortion, a pseudo-rheumatismal articular form, a neuralgic and paraplegic form, and a renal form with hæmaturia. He recommends that while intravenous injections may be given in all tolerant cases, especially in the primary stages, subcutaneous or intramuscular injections should be given in all weakly subjects, especially pregnant women, to avoid the occurrence of accidents.

NINETIETH ANNUAL MEETING

OF THE

British Medical Association.

Held at Glasgow, July, 1922.

PROCEEDINGS OF SECTIONS.

SECTION OF PUBLIC HEALTH.

A. K. CHALMERS, M.D., F.R.F.P.S., D.P.H., President.

PRESIDENT'S INTRODUCTORY REMARKS.

1888-1922:

A PLEA FOR THE STUDY OF BIOLOGY IN
RELATION TO PUBLIC HEALTH.

A DESIRE to review the history of medicine in its preventive aspects during the thirty-four years which have come and gone since last our Association met in Glasgow is almost inevitable. But that it can be done adequately in the time at my disposal would require a power of focusing for which I claim no qualification. My purpose rather is to indicate a few contrasts; to ask how far the years between have established the views of our predecessors; whether the horizon has lifted and disclosed objectives hidden from them; most of all, to ask whether the same spirit of service which inspired our predecessors remains with us who aspire to follow them. A comparison of the record of subjects discussed at the former meeting with those of the present might alone supply the answers.

PUBLIC HEALTH THIRTY YEARS AGO: A CONTRAST.

Illustrations of the contrasts are readily found. The mean population of Scotland during the eighties decade was 3,880,610; at the last census it was fully a million more. In the former period the average death rate was 19 per 1,000. Had this rate obtained in recent years, we should have had almost 20,000 more deaths annually than were registered during the period 1916-20, although these included periods of pandemic influenza of great intensity. The large towns of Scotland have now (1916-20) a lower average annual death rate (16.34 per 1,000) than had the rural districts and smaller town areas in the later eighties (17.28 per 1,000).

The infant mortality during the eighties rose from 112 per 1,000 births in 1881 to 130 in 1890; during the last ten years the highest rate was 126 (in 1915), in 1920 it fell to 92, and was 97 and 99.8 in 1916 and 1918. But the birth rate has also fallen from an average of 32 during the eighties to 25.4 in the years 1911-15 and 22.7 in 1916-20. One result of this is that already by 1911 the proportion of the population over 15 had increased from 63 to almost 68 per cent. In other words, that portion of the population which has a steadily although at first slowly increasing death rate, is gradually increasing in volume, so that it now forms fully two-thirds of the whole.

Further contrasts may be drawn from the field of epidemic diseases. I need not recall the shrinkage in what were then called the major infections which has run parallel with these changes. The recurring prevalences of typhus fever, which formed so marked a feature of the epidemic history of the middle of last century, had largely ceased by the eighties decade, but even so it caused about 90 deaths annually in the years 1886-90; while in recent years (1916-20) the deaths averaged only one-tenth of that number, notwithstanding the great prevalence of the disease in Eastern Europe and Russia and in the Balkans during the war years and afterwards, and the many migrations both of soldiers and civilians determined by the war. Again, the deaths from enteric fever, which averaged 765 annually in the period 1886-90 and in three earlier years of the decade had exceeded 1,000, now average only just over 100 annually (109); in the former period over 7,000 deaths were on an average ascribed annually to pulmonary tuberculosis—now less than 5,000. Scarlet fever is less fatal, but its prevalence oscillates through long intervals; while measles and whooping-cough seem unaffected by any measures hitherto undertaken for their control.

Passing for a moment from results to machinery and equipment, there was, in those days no county sanitation—no

general provision of hospital accommodation for infectious diseases—a limitation, indeed, of the term "infectious disease" to the acute specific fevers and exanthemata. There was no Notification Act of general application; bacteriology was in its infancy; vaccine and serum therapy had to wait some years before their enrolment began. The part played by insects in the spread of disease was almost unsuspected.

The first Public Health Act for Scotland had already been twenty-one years on the Statute Book, but the sanitary enfranchisement of the rural populations was not yet accomplished, while the burghs were struggling with conditions for which the general Act provided no adequate remedy. So sanitary legislation formed the theme of the President, Sir Henry Littlejohn, and the late Sheriff Spens urged the creation of a Minister of Health. County sanitation became possible with the passing of the Local Government (Scotland) Act of 1889, and a Burgh Police and Public Health Act in 1892 gave a new stimulus to the sanitation of towns. The Housing Act of 1890 had barely begun to form round the nuclei supplied by the Torrens, Shaftesbury, and Cross Acts and some local ones of earlier years.

In another direction the horizon was limited by our insular position. Exotic disease in the form of cholera, it is true, had reached our shores so recently as 1866, and although the Venice Convention dated from 1857 it was not until 1900 that a limited outbreak of plague among our own people startled us out of our insular complacency and helped to stimulate the formation of port local authorities as a means of protecting our shores against sea-borne disease. More than all, and of special importance in view of the future, preventive medicine broke through the old barrier of insanitary surroundings and insisted on regarding the individual as himself the contributor to much of the disease which imperils our well-being, and brought venereal disease within the purview of administrative action.

THE FRUITS OF ADMINISTRATIVE ACTION.

One field after another has thus been brought within the scope of regulated effort, and may claim some consideration at least in a review of the causes of the decline in the death rate which has gone on contemporaneously with their application to administrative purposes. But when we endeavour to assess the precise value of any individual factor when many are operating, error may readily occur. Legislation and administrative effort are valuable adjuncts, but they are not the only factors which control disease. How, for example, are we to explain one of the profoundest problems in the history of tuberculosis in this country? I mean the sudden change in the direction of the death rate which took place in Scotland in the middle of the seventies. For fully a decade before the last meeting of the Association here the tuberculosis death rate was undergoing reduction at a rate which is not now equalled. No concerted administrative action was being directed against its prevalence—I do not, of course, forget the early clearance schemes, but they were wholly, I think, confined to the towns, whereas the fall was general—and the subject does not, I think, occur in the published record of the former meeting. On a former occasion elsewhere I endeavoured to associate the antecedent increase in the rate with the migration to the towns which was so marked in Scotland in the middle of last century, and its subsequent fall with the growth of a locally born population endowed with greater resistance to local conditions than their immigrant parents; but the lack of information regarding the actual proportion of incomers among the population somewhat altered the apparent significance of the contrast.

If I seem to labour the point it is for the purpose of asking whether, in contemplating the superstructure we erect for public health purposes, we do not too often forget that Nature is silently at work often doing better for us than we know, and that our efforts will best be directed towards the control of disease when we know more of Nature's methods of adapting life to the varied conditions under which it exists. For Nature is a skilful nurse, and our best work will be done by a close study of her methods. Tuberculosis and infant mortality, indeed, form two illustrations of the play of biological forces but dimly apprehended. To these we might well add a third in the decline of the birth rate, and the common warning I think they give is against a too ready acceptance of the view that their decline is to be ascribed solely to administrative action on the one hand, or acts of volition sometimes called prudential on the other.

In the first decade of a falling death rate it was still too early to see that a process akin to geological denudation was in progress, and it was not, indeed, until the present century had begun that a high infant mortality rate was disclosed as at once persistent and refractory. So also with regard to tuberculosis, the discovery of the bacillus was still too recent for frank recognition of its rôle as an infecting agent to influence action for the prevention of its spread. But in connexion with both it is worth remembering that the fall in the general death rate coincided with the growth of our foreign meat imports, and that the fall in the infant death rate of this century is occurring among the children of those who grew up under the improved food conditions which these imports tended to make general.

THE NEW HORIZON. Infant Mortality.

Since the present century began we have had in succession organized movements for the welfare of mothers and children, for the reduction of tuberculosis and the treatment of venereal disease. All of these reach down by separate channels to the roots of our social structure, but each also presents aspects which are biological before they are social. It is the recognition of this factor as influencing the whole field of preventive medicine that I think fills the future with hope. Let one but try to envisage the biochemical changes which set in directly the newly born child draws its first breath and produce within a few days closure of the ductus arteriosus and then ask himself whether Nature's alchemy is limited to this single and marvellous process by which the circulation becomes adapted to the demands of an air-breathing organism. Here the structural change is concrete and obvious, as is the alteration in physiological function which accompanies and depends on it. And if we ask ourselves regarding the great volume of infant deaths ascribed to immaturity under a diversity of names (prematurity, birth debility, and some others), mainly occurring in the first weeks of post-natal life, contributing about one-third of the total infant death rate, and distributed with apparent impartiality through every social group, the closed ductus arteriosus may stand as a type of the changes which in falling cause the death of so many newly born children.

Venereal Disease.

In venereal diseases again biology and disease are curiously intertwined. Treatment centres attract many social and biological types, from the youth whose early training has failed to develop habits of self-control which should find their beginning in the physiological inhibitions of the nursery, to the habitué who presents himself with a reinfection many times repeated. If we accept the one as but a reckless adventurer on the sea of desire who wilfully discards the rudder of self-control and abandons himself to the storm winds of passion, how can we regard the other but as an atavistic "throw-back" to a much earlier civilization which looked at the marvel of reawakening nature through the eyes of the phallic worshipper? Superficially these two men may be regarded as differing only in the degree of freedom with which they permit themselves to follow antisocial practices; in reality, although both are of one generation, from the point of view of social development they are separated by some thousands of years.

Tuberculosis.

I need not in this connexion anticipate the questions which surround the administrative treatment of tuberculosis, as full scope will be afforded for discussion in the joint conference with the Tuberculosis Section to be held during our meetings. But this much may be said on the general outlook, that no completely satisfactory explanation has yet been advanced of the change in direction of the death rate from all forms of tuberculosis which began with some suddenness in the mid-seventies, before schemes for its administrative control were in operation—before, indeed, widespread effort at sanitary reform was in operation beyond the town areas. Yet the fall was general and has been continuous, and in its beginnings at least must have been the expression of causes widely operative and not confined to particular sections of the population. One looks again for a biological explanation, whether it be in a reduced virulence of the organism or in increased resistance of the population as

a whole. And it is a tempting hypothesis to regard as among several factors of wide application the new sort of nitrogenous food supply, then beginning to be available by the importation of foreign cattle.

It seems to me that Loeb's investigations into the ductation of artificial parthenogenesis have opened up entirely new aspect of the relation of cell life to the salt of the fluids in which it is bathed, and may be found lately to have some bearing on the everyday question of food supply. For the present the adequate feeding of population seems to me one of the public health problems awaiting solution. Actual food shortage—that is, famine a general sense is unlikely in these islands in peace times, reduction below subsistence diet among great masses of population is a possibility in times of trade depression, our machinery for meeting this is defective.

Industrial Fatigue.

In still another direction the horizon is lifting. Of recent years an entirely new field of research has been opened up the application of physiological and psychological tests to discovery of the causes of industrial fatigue.

Diseases referable to particular industries have long been recognized, but the need for correlating the rhythm of work to the physiological rhythm of the worker, if not entirely new conception, is at least a new application of doctrine which Collis and Greenwood aptly, I think, illustrate by the picture of a boat race where the rowers "go to piece" if the stroke is too slow to permit of sufficiently rapid breathing, and, on the other hand, cannot breathe efficiently if the rate exceeds 40 a minute. And as the conditions which both efficiency and fatigue depend include the hours of the worker, his food, habits, and recreations, as well as hours and method and conditions of labour, we seem at last to be within sight of a time when employer and employed meet on a common platform and discuss the hours and conditions of labour in the light of the physiological conditions which maximum efficiency may be reached with a minimum of fatigue.

CONCLUSION.

In conclusion, it would be unwise to forget that many the aims of preventive medicine come under the general criticism so often applied to all schemes of social welfare. You are familiar with the argument: Racial fertility is in inverse ratio to the human value of the stock, and much of the work of preventive medicine is preserving the inefficient. Saved from the incursion of barbarian hordes, civilization, by accentuating the effects of a differential selection, is creating a race by an indiscriminate preservation of many unfit lives at the other end of the social scale. Natural processes of selection, we are told, are being arrested, and we are sitting up civilization from the bottom.

But biological fitness to carry the burden of civilization exists across all social stratifications. In America, because of the enormous complexity of the social problems which immigration is producing, they are probably reaching conclusions more quickly than in this country. During the late war the United States army authorities applied "intelligence tests" to nearly one and three-quarter million recruits, and "some of the best scores were made by illiterate ignorant Southern mountaineers who had never before been outside their native valleys. In other words, primitive conditions had held back a high-grade Anglo-Saxon stock, but the intelligence was there, passed on from generation to generation, and only awaiting a favourable opportunity to display itself."

It is right to state, however, that the main thesis of the author from whom I have taken this extract is the biological decline which threatens civilization, and the volume is a reasoned statement of the evidence which the work of Galton and Whetnam among others in this country has made familiar to us.² But the quotation is of value, I think, if it serves to stimulate us anew to think what "primitive conditions" are and induces us to ask how much biological capital of permanent value to the race is locked up in the unfavourable environment in evidence everywhere awaiting the opportunity which it is one of the aims of preventive medicine to afford.

PORT SANITARY ADMINISTRATION :

S DEVELOPMENT AND ITS RELATION TO PUBLIC HEALTH
IN ENGLAND AND WALES.

BY

CHARD J. REECE, C.B., M.A., M.D., M.R.C.P., D.P.H.,
Vice-President of the Section.

One of the primitive instincts of mankind is to protect itself from the possible introduction of pestilence. It is probable that in the very early period of civilization, when men first consorted together in communities, some sort of crude code existed for dealing with obviously diseased persons and outbreaks of disease with the object of preventing the spread of sickness. The best known example of such a code is given in the thirteenth and fourteenth chapters of the Book of Leviticus, which lay down the procedure for certain measures that should be carried out in regard to "lepers," and for their isolation.

As time went on and communications between countries became established and the trade of the world expanded, the adoption of methods designed to prevent the introduction of pestilence became general. These methods varied from time to time in accordance with the views that prevailed as to the manner in which disease was spread, but it was not until the middle of the nineteenth century, following the discoveries of Pasteur, Pollender, and Bavaine, that methods of "quarantine" became established on a scientific basis. The word "quarantine," although its modern practice differs materially from that of mediæval times, is still retained to indicate those restraints placed on free intercourse on land or sea, and those measures taken to protect the public health by preventing the introduction of disease.

The first attempt to enforce maritime quarantine probably took place in Venice. In 1448 the Venetian authorities drew up a code of quarantine regulations which were directed against the introduction of plague into their city, and for centuries this code formed the basis for similar codes in other countries.

The study of the various measures adopted from time to time is an interesting one. It is, however, not possible to give a detailed account of them in this paper. Of the older methods Dr. John C. McVail wrote :

"Regarding the prevention of plague invasion in olden times, some places adopted measures which would not be permissible in the present day. The City of Aberdeen was nothing if not thorough in this matter. As recorded by Dr. Creighton, the townsmen in 1585 followed the Draconian example of Good Queen Bess at Windsor some twenty years before. They erected three gibbets, 'one at the mercat cross, one other at the Brig o' Dee, and a third at the haven mouth, that in case any infectit person arrive or repair by sea or land to this burgh, or in case any indweller of this burgh receive, house or harbour, or give meat or drink to the infectit person or persons, the man be hangit and the woman drownit.'"

In 1636, when the fear of plague occupied the public mind of this country, the Royal College of Physicians of London drew up certain directions, the second of which states that :

"It is likewise necessary that there be care taken that neither man nor goods may come from any suspected places without a certificate of health or else either to be sent suddenly away or to be put in the pest house (or such like place) for 40 days, according to the custom of Italy."

It is interesting to note that it was in August in this year that the distinguished Fellow of the College, William Harvey, who first described the movements of the heart and the circulation of the blood, was interned in a lazaretto at Treviso while on his way to visit the English Ambassador, Lord Basil Feilding, at Venice. His letters written from the lazaretto show how deeply he resented his detention.

It was not until 1710 that the first Quarantine Act was passed in England. Prior to this, regulations to prevent the introduction of disease into this country by placing restrictions on the free movement of persons and goods had been issued by an Order of the King in Council, and the Act of 1710 was passed hurriedly under the influence of panic occasioned by the prevalence of plague in the Baltic. It was followed by amending Acts, one of which gave power to order vessels coming from infected places, or laden with goods from such places, or having on board any infected persons, to be burnt, together with the whole or any part of the cargo. In 1752 a new Quarantine Act was passed under circumstances not associated with panic due to a prevailing epidemic. By

the provisions of this Act all vessels infected with plague were required to proceed to one port—namely, New Grimsby. At that period reliance against the introduction of plague was placed on the 'opening out and airing' of cargo, and this principle was adhered to; the landing was prohibited of goods or merchandise that had been brought from suspected areas and which had not been sufficiently opened and aired at the lazarets at certain specified places.

These quarantine regulations placed restrictions on the commerce of the country, and it was recognized by Parliament in 1752 that "the present system of quarantine by airing goods on hoys and vessels is not well calculated to prevent infection, and is inconvenient and expensive to the merchant," and later money was provided by Parliament to establish a lazaret for the performance of quarantine by persons and goods at Chetney Hill, in the county of Kent (in what is now known as Milton Rural District). This lazaret was never completed.

In 1783, plague became prevalent in Poland, and the Privy Council ordered vessels coming from that country to perform quarantine for forty days. Even in those times we were dependent to a certain extent on imported foodstuffs and some of the vessels from Poland were laden with grain. In a short time Edinburgh was threatened with a corn famine, and an order was hurriedly issued to allow vessels laden only with grain to discharge their cargoes without any quarantine restrictions, provided that the master of the vessel certified on oath that the crew of his vessel were free from infection, and that his vessel had not communicated with any vessel from an infected place.

With increasing overseas trade the impracticability of enforcing quarantine measures which seriously interfered with commerce became more and more evident, and this brought about a revision of the quarantine system. In 1824 a select committee appointed to inquire into the circumstances associated with our foreign trade drew attention to the serious financial burdens imposed on shipping by the quarantine charges, and in particular one case was cited in which there was no sickness on board the vessel yet nevertheless the quarantine charges exceeded 90 per cent. of the value of the cargo.

The report of this committee was followed by the passing of the Quarantine Act of 1825. This Act prescribed precautionary measures to prevent the introduction into this country of diseases such as plague, cholera, and yellow fever—diseases from which the country was free and which existed in countries with which we had maritime communications. Under the provisions of this Act and of the Orders in Council of the same year, all vessels coming from the Mediterranean or from the West Barbary on the Atlantic Ocean with clean bills of health, or any vessel from ports of Europe outside the Mediterranean or from America, were required to perform quarantine at various places specifically named according to the vessel's port of destination. The duration of quarantine was for fifteen days after arrival at the port or after discharge of cargo into "floating lazarets" or lighters, according to the nature of the cargo. All vessels whose bills of health were not "clean" had to perform quarantine at Standgate Creek in the Thames, or at Milford Haven. This Act remained on the Statute Book until repealed by the Public Health Act of 1896.

But long before 1896, as Dr. Bruce Low has pointed out, the Quarantine Acts had been regarded as a failure, and it was even then contended that quarantine could give but a false security for the purpose it purported to accomplish. In 1849 a suggestion was made that existing quarantine establishments should be abolished and that reliance should, in future, be placed exclusively upon the protection afforded against the spread of imported infection by a system of local sanitary improvements. From that time onwards the opinion of British sanitarians has been that the best way to prevent the dangers arising from imported infection is to maintain a high standard of sanitation and administration at our ports and inland districts, but it took the English advocates of the abolition of quarantine about twenty-five years to make any impression on other nations.

In this country maritime quarantine has been applied only to cholera, plague, and yellow fever—all three diseases of foreign origin. Against cholera the full quarantine procedure has not been enforced since 1858. Considerations of time and space do not permit of even a brief account being given of the

arguments adduced in favour of the substitution of "medical inspection" for "quarantine" and the steps taken to bring about the change.

In the year 1871 the Privy Council was succeeded as the central health authority by the newly formed Local Government Board, and in 1872 an Act was passed dividing the whole of England and Wales into urban and rural sanitary districts. The Board was given power to constitute port sanitary authorities for any customs port or for part of a customs port, and the provisions of this Act were reproduced with modifications in the Public Health Act of 1875, which consolidated and amended the various laws relating to public health in England and Wales.

The system of quarantine of ships formerly relied on to prevent the introduction of infectious disease into this country from abroad was replaced by the system of port sanitary administration so established, and by subsequent legislation. Under these various Public Health Acts every local sanitary authority whose district abuts on any part of the coast or on a navigable river is a riparian authority. Under Section 287 of the Public Health Act, 1875, the riparian authorities of the principal customs ports have been constituted port sanitary authorities by Order of the Local Government Board either singly or as joint boards. The expenses of the port sanitary authorities are met in the same manner as those of local authorities under the Public Health Acts. The London Port Sanitary Authority was established by a separate enactment.

It should be understood that the coastline of England is divided into several customs ports, and in a customs port may be comprised one or more port sanitary districts, or other sanitary districts not included in a port sanitary district. These other sanitary districts may be urban or rural, and are known for administrative purposes as riparian sanitary districts. In all customs ports there are boarding stations, appointed by the Commissioners of Customs and Excise, at which ships arriving from "foreign" are required to bring to for boarding by customs officers. The precise position of the official boarding station of the customs is clearly defined at each port. There are usually two such boarding stations at each port, one being "for vessels infected" or "suspected," as defined in Article I, Part I, of the Order of the Local Government Board, dated September 9th, 1907—to which is sometimes added "and vessels with dangerous infectious disorders on board," and the other "for all other vessels." By the latter is meant the place where the vessel is bound for discharge of cargo or passengers and for loading. In practice, vessels which are known and admitted by the master to be "infected" or "suspected" bring to at the customs boarding station. In other instances the port medical officer of health may inform the customs that he wishes to inspect vessels coming from certain ports or places where infectious diseases are prevalent, and in such circumstances the vessels are intercepted at the boarding station by the customs and detained for examination by the port medical officer of health. Otherwise the vessel goes straight to her place of "mooring, discharge or loading."

The port sanitary authorities exercise over the waters of the port and over the shipping therein the same functions as sanitary authorities exercise on land, with certain additional duties; and for the purpose of carrying them out all port sanitary authorities must appoint a medical officer of health and a sanitary inspector, and if necessary assistant sanitary inspectors, some of whom must have special qualifications as food inspectors, and provide isolation hospital accommodation for cholera, plague, small-pox, and other infectious diseases, either directly or by arrangement with other local authorities.

Cholera, plague, typhus fever, and small-pox are four among many diseases that may be introduced into the country from abroad through the agency of shipping. The far-reaching effects of the great war have extended to and influenced the prevalence and distribution in the world of these four diseases; the study of their behaviour under war conditions and afterwards is receiving the earnest attention of epidemiologists. We realize that these conditions have placed this country in a position that renders it more liable than usual to the introduction of disease.

It is known that *cholera* has established itself for the time being in certain parts of Russia and the Ukraine. The presence of this disease in Asia, or even in Europe in the

neighbourhood of the Black Sea, has not in the past been source of more than potential danger to this country. The short incubation period of cholera, the long sea passage through the Mediterranean Sea, or even the overland route finish with a short sea voyage to this country, afford ample time for travellers to develop symptoms of the malady before reaching this country. It is a different matter when cholera appears in Europe in the area of the littoral of the North and Baltic Seas.

The circumstances of the war have led to the spread of these diseases, and at the present time there is widespread prevalence in Europe of these diseases. Of these the most important is *typhus fever*. Recently a man coming from Warsaw developed the disease immediately after his arrival in London, and cases of typhus fever have occurred in Birkhead. But at the moment there is no typhus fever in England and it will be realized that the increase of traffic with typhus infected countries renders very strict precautions necessary to maintain this freedom.

Small-pox was present in many of the war zones and in armies; and incidentally the civil population in these zones experienced attacks of small-pox limited in proportion to extent of their protection by antecedent vaccination. Prior to the war this country had little fear of the possible introduction of small-pox through the agency of returned soldiers; for, in the past, British troops were vaccinated on joining the colours. During the war vaccination or revaccination was not made compulsory on men of the Territorial Force or of the new army; though the great bulk of our soldiers, owing to their common sense, willingly accept this protection against small-pox. Nevertheless, this protection was not adopted by all, and, during the year 1919, outbreaks of small-pox occurred in England and Wales which were traced directly to returned soldiers.

The possibility of the introduction of *plague* through human cases is not very great; its introduction is more likely to occur through infected rats, brought on vessels to our ports, gaining access to the shore and conveying the infection to the population on land. The revision of the International Convention may have the effect of extending the duties of port sanitary authorities in the direction of rat destruction.

In addition to the four diseases already mentioned there are others intimately associated with shipping, with which port sanitary authorities have special concern. Two of these may be mentioned, for example—*beri-beri* and *malaria*.

Expert inquiry as to *beri-beri* brings to notice preventable conditions caused by improper dietary of the sailor. *Malaria* inquiries direct attention to preventable conditions of exposure to dangerous malaria infection—for example, in West African ports. In addition, humanity and the interests of the sailor require that cases of such disease, although not infectious in the ordinary sense, should receive hospital treatment at our ports.

The legislative machinery for the prevention of the introduction of cholera, yellow fever, and plague into this country is comprised in an Order of the Local Government Board "Regulations as to Cholera, Yellow Fever, and Plague; Ships arriving from Foreign Ports"—dated September 9th, 1907. These regulations comply with the terms agreed upon at the International Sanitary Convention of Paris, 1903. Certain modifications in the terms of the 1903 Convention were made by the International Sanitary Convention of Paris, 1912, but owing mainly to the war, the ratification of the latter Convention was delayed and was only recently completed. A further revision of the International Sanitary Convention is now in progress.

So far as the mercantile marine is concerned, one of the most important duties imposed on port sanitary authorities is that of dealing with conditions adversely affecting the health of crews and with the insanitary condition of ships.

The question often arises whether the port sanitary authorities should exercise its powers as to nuisances on board ship where structural alterations would be required for the abatement of the nuisance, or whether they should leave the matter to be dealt with by the surveyor appointed by the Board of Trade. Clearly the powers of the surveyors are concurrent with those of the port sanitary authority; there are many cases where a nuisance on shipboard requires abatement which does not come within the provisions of the Merchant Shipping Act. The port sanitary authorities are in no way responsible, not

indeed is the Ministry of Health, for securing adequate facilities for the medical or surgical treatment on shipboard of sick persons.

When dealing with the local sanitation of harbours, waterways, docks, and other shore premises within their jurisdiction, port sanitary authorities are hampered by lack of adequate powers to deal with accumulations of refuse, scavenging, and like matters. From the public health point of view there would be advantage in investing these authorities with wider powers than they now possess in regard to such matters.

The examination of imported foodstuffs, which is of very great importance, is regulated by Orders made under the Public Health (Regulations as to Food) Act, 1907, and has effected improvement in the national food supplies by preventing the importation of undesirable and unwholesome food.

Other special duties of port sanitary authorities are the protection of shellfish from sewage pollution and the sale of shellfish for food from beds and layings that are known to be polluted. The fall in the enteric fever attack rate in this country can be attributed in part to the prevention of specifically infected shellfish reaching our markets, etc.

If the various duties performed by port sanitary authorities are considered seriatim it will be seen that except in regard to inspection of food the duties are in part national and in part local; and this is represented in the financial arrangements made for the performance of the duties.

In 1920, the Government agreed to a grant-in-aid being made to port sanitary authorities of 50 per cent. of their approved net expenditure. This grant is subject to regulations prepared by the Ministry of Health with the approval of the Treasury, and the Ministry can withhold or reduce the grant in cases where a minimum degree of efficiency is not attained. The cost of a serious cholera, plague, or typhus epidemic, whether at one of the ports or inland, might easily be far greater than any expense to which the country or the shipping industry is put by reason of an efficient port sanitary administration. This point is so self-evident that it need not be laboured.

Desired progress in regard to infectious diseases could not be obtained without conferring on port sanitary authorities and their officers some additional powers and duties. Draft regulations were drawn up and submitted to the principal port sanitary authorities, and a deputation was received at the Ministry of Health at which the object and scope of the regulations were discussed and agreed to. As a result of most careful consideration the Port Sanitary Authorities (Infectious Diseases) Regulations were issued in 1920, and additional duties as well as powers were imposed on port medical officers of health. Probably the most important matter dealt with in these recent regulations is the danger of the spread of infectious diseases by vermin, especially the deratization of ships, which is one of the most urgent problems that concern port sanitary authorities.

In this country the fumigation of vessels for the purpose of destroying rats is usually carried out with sulphur dioxide gas generated by burning ordinary sulphur in pots, or sulphur candles, under suitable precautions against fire. This is an efficient fumigant when properly employed, and gives good results in so far as the destruction of rats is concerned, but it damages machinery and spoils paintwork, and for this reason a passenger vessel has often to be redecorated after undergoing sulphur dioxide fumigation. A number of vessels have recently been fumigated at British ports with hydrocyanic acid gas, which, unlike sulphur, has no harmful effect on machinery or paintwork, but, needless to say, this method of fumigation has to be used with the very greatest care owing to the danger to human life involved in the process.

It is understood that at Rotterdam and other ports in Holland trial is being made to fumigate vessels by means of a liquid known as "cyclon," which is composed of methyl cyano-formate 90 per cent. and methyl chloro-formate 10 per cent. The liquid volatilizes rapidly when sprayed into the air, the methyl cyano-formate giving off hydrocyanic acid gas and the methyl chloro-formate a gas which is intensely irritating to the eyes and respiratory surfaces, and this serves to give warning of its presence before the hydrocyanic acid gas reaches dangerous proportions in the atmosphere. The cyclon is distributed through the space to be fumigated by means of specially constructed brass "watering" cans, each fitted with a fine rose. This method appears to possess advantages over the

ordinary methods of hydrocyanic acid gas fumigation, but as yet it is only in the experimental stage.

As a general rule before the war the port medical officer of health acted as the medical inspector of aliens on behalf of the Home Office, by whom he was remunerated for his services. The only aliens medically examined were steerage passengers, and then only those entering the country on ships carrying twenty or more such passengers were liable to medical examination. No definite instructions were issued to the medical inspectors of aliens as to the medical standard to be adopted. During the war the medical inspection of aliens fell into abeyance.

After the armistice the conditions under which aliens should be permitted to enter this country were the subject of consideration by the Aliens and Nationality Committee, which met under the auspices of the Home Office. As a result of this Committee's deliberations, the Aliens Order of 1919 was issued and came into operation on September 1st, 1919. Later, when the Aliens Restriction (Amendment) Act, 1919, was passed, this Order was superseded by the Aliens Order of 1920, which came into operation on April 1st, 1920. Under these Orders the Home Office is responsible for the exclusion of any alien from this country, and all aliens, whether first-class passengers or otherwise, are liable to exclusion on medical grounds or for other reasons which are essentially Home Office affairs.

All aliens are now liable to medical inspection at one or other of the thirteen ports scheduled in England and Wales for the landing of aliens, and the Minister of Health, with the concurrence of the Secretary of State, is empowered to appoint "medical inspectors" at each scheduled port and to issue instructions to them.

The port sanitary authorities concerned agreed to their medical officers of health acting as medical inspectors of aliens, and a scheme was devised and put into operation. During the two years that the scheme has been working it has been subject to local inspection by medical officers of the Ministry, and conferences have been held with the local medical officers and with the officers of the Home Office, who are responsible for the aliens' work of that department. The result of the experience gained is now under consideration with a view to determining whether any amendments are desirable.

Considerations arising from the foregoing.

In reviewing our port sanitary administration from the points of view of the prevention of the introduction of disease into the country and the effect of this administration on our commerce, it will be realized that restrictive measures on the movements of ships, persons, and cargoes that are regularly and satisfactorily carried out and are well known to shipping companies and the travelling public to be in operation, are less prejudicial to commerce and to international relationships than the disturbance to trade and commerce that follows an outbreak of pestilence.

The history of the world shows that when a disease which is capable of developing epidemic proportions and proves rapidly fatal to a large proportion of those attacked by it has been absent for several years, there is a tendency for the precautions against its introduction to become relaxed or to fall into desuetude. On the other hand, when such a disease suddenly reappears in pandemic form after an almost complete absence for a long period of time, countries, provinces, or cities take steps to prevent its introduction into their midst that are in excess of actual requirements. It is necessary to avoid laxity on the one hand and scare and panic on the other.

No measures short of absolute national seclusion can be relied on to prevent the introduction of pestilence, and this seclusion would cut off the country from its means of existence. It is not suggested that the system of medical inspection now in operation is "water-tight" and that no leakage can take place; it is realized that under certain conditions a chance case of disease may find its way inland and that in such instances we have to rely on our inland sanitary administration to prevent diffusion of infection. Nevertheless grave responsibility to the public rests on port sanitary authorities to maintain a high standard of efficiency in their administration.

It is not the known but the unknown that we are afraid of. Once we are satisfied that we are fully apprised of the health conditions of an incoming ship the necessary steps can be taken to deal with the vessel. The object of the inquiries made of

the master on the arrival of his vessel by officers of customs and officers of the port sanitary authority is to obtain knowledge of the sanitary condition of the vessel and of the happenings during the voyage, in order that reasonable and efficient steps may be taken to prevent spread of disease. The officers of customs, when putting the health questions to masters of incoming vessels, do not board the vessel. If the replies are satisfactory they board for excise purposes. In the event of the replies proving unsatisfactory, the customs officers, however, have the power to detain a vessel for visit by the port medical officer of health.

These arrangements have worked well in the past, but it is necessary from time to time to consider whether they can be improved, and if so, in what direction. At present a large proportion of merchant vessels are fitted with wireless apparatus, and therefore in the future it may be found feasible for information as regards health conditions of an incoming vessel to be transmitted by wireless from the vessel to the port for which she is bound or to some centre whence the information can be forwarded to the home ports. It would then be possible to give the master instructions as to taking his vessel to the official mooring station or to direct him to bring his vessel straight into dock. Further, the master could be advised as to the steps he should take to deal with the health conditions affecting his ship, and such advice would be particularly valuable when a surgeon is not carried on a vessel. The port sanitary authority, warned beforehand, would be in a position to take the requisite action to deal with the vessel immediately on her arrival.

During the last quarter of a century considerable improvement has taken place in the general sanitation of vessels, but much still remains to be done in this direction. Experience shows that many of the existing defects are the result of insufficient consideration and lack of expert advice. In many cases it would cost no more to construct the crew's quarters on sound hygienic lines than on the faulty lines which at present are too often met with. This condition of affairs would be rectified were the plans of all new vessels submitted for consideration by an expert in marine hygiene.

It has to be borne in mind that for the success of our port sanitary administration we rely to a great extent on the integrity and probity of the officers of the mercantile marine, and for this reason, if for no other, they are entitled to sympathetic consideration and to all possible assistance in carrying out the duties imposed on them for the protection of the public health.

DISCUSSION.

Dr. W. F. DEARDEN (M.O.H. Port of Manchester) thanked Dr. Reece personally, and on behalf of port medical officers generally, for his excellent summary of port sanitary administration. Too little was known by the general public of this "first line of defence," and his paper would help to remedy the defect. Early measures were too severe and restrictive, they hampered trade—hence their failure. The new regulations of 1920 had much improved the powers of port medical officers to control the importation of infectious disease, but there were still a few loopholes which required filling up. As examples of these he quoted the difficulty of ascertaining accurately the destination of contacts from an infected vessel, the responsibility of the ship's master to report cases of infectious disease which he was unable to diagnose, and the lack of facilities for isolation of cases on board ship. The port medical officer should be able to deal with insufficient and insanitary latrines provided for the use of seamen on the quays.

Dr. W. W. KING (U.S. Public Health Service) spoke on behalf of the Surgeon-General of the United States Public Health Service, Dr. H. S. Cummings, who was unable to accept the invitation to be present. In Dr. Reece's address he had found many parallels in the duties, powers, and limitations of the port health officer. Quarantine he likened to a sieve intended to pass the harmless and stop the harmful. It was imperfect, and there was a constant endeavour to strengthen it without interfering with travel and commerce. When the fear of an epidemic occurred there was an opportunity for improvements in the service, and such was the case in America in 1893 during the prevalence of cholera in European ports. It was then that men were first stationed

at American consulates abroad to deal with the sanitation of vessels, passengers, and crews destined for United States ports. Such health officers occupied the important position of outposts in the first line of defence.

Major R. W. H. JACKSON (R.A.M.C., ret.) gave his personal experiences as a former Army Health Officer both at home and abroad. As special health officer in Calcutta in 1903 he could testify to the difficulties of diagnosing plague. He had had experience of cholera and small-pox in Karachi, yellow fever in the West Indies, typhus in Ireland, and leprosy in the East and West Indies. He had found that severe penalties for concealment of disease on board ship defeated their object. Enforcement of cleanly habits and a supply of wholesome water were the two great difficulties encountered in dealing with merchant vessels in foreign and tropical ports. He thought wireless telegraphy would be a useful adjunct in notifying sickness on board.

Dr. J. C. McVAIL expressed the opinion that to prevent interference with trade the ideal was to have the country made as far as possible sanitarily invulnerable to invasion. A main difference between the American and British systems was that the former took protective and preventive action at the ports of departure of immigrants, even though the amount of emigration from all parts of the world was very much greater to America than to Britain. In Scotland the only joint port authority was that of the Clyde. Each port on the Forth was independent, and therefore responsible in its own area only.

Dr. HERNERT JONES referred to the excellence of the work carried out by the port sanitary medical service as the reason why it might not be well known. He was of opinion that the transmission to inland medical officers of health of notices giving the addresses of contacts on infected vessels was of very great use, and he hoped there would be no question of discontinuing the practice.

Dr. REECE, in reply, stated that it was unfortunate that only emigrant ships were obliged to provide hospital accommodation. Contact on board a ship at sea was very intimate, but attempts were being made in the newer vessels to disperse the sleeping quarters of the crew. The tracing of persons from infected ships was admittedly a difficult matter, and he could see no satisfactory solution of the difficulty. Much depended upon the probity of the master, and he deserved consideration for the many responsibilities which he undertook.

THE ECONOMICS OF PUBLIC HEALTH.

BY

LIEUT.-COLONEL F. E. FREMANTLE, O.B.E., M.P.,

Consulting County Medical Officer of Health, Herts.

THE need of economy after the war, both in national and private life, is so obvious that there is a danger of expenditure being reduced without regard to the return expected of it unless that return can be shown in pounds, shillings, and pence. This is especially the case in measures that aim at the promotion of mental and moral values, for whereas currency is but the financial language of material value, and economy in public affairs deals with material currency alone, mental and moral values have yet no counterpart in monetary language. In the promotion, therefore, of the public health the many intellectual and moral advantages that result from health cannot be represented in financial terms, and there is a danger, both in national and local government, of necessary services being curtailed as if the moral values were a matter of no importance. In certain other fields—as in education and in religious matters, for instance—this is even more serious than in public health, for in those spheres no material profit can be definitely shown as a result of suggested expenditure. But in public health we have this advantage, that there are definite material gains from wise expenditure which can be shown to be reduced by a reduction of that expenditure. This paper sets out to show—or rather to suggest as a basis for further study—the material loss occasioned by physical sickness and disablement and the material advantages that may be obtained, or have been obtained, from improvements in the public health. We

recognize definitely that this is only part—perhaps only a small part—of the advantages obtained and obtainable. But with regard to these material advantages, much slipshod language is commonly used in support of the measures taken or proposed. The advantages claimed are usually set forth only in general terms, which do not appeal to the business man or to those responsible for public finances, and the cynic, who plays a most useful part in these hard times, has an overwhelming advantage unless the case for the material advantages of the public health services can be set out in the common language of finance.

In reconstruction of our public and industrial life the object must be to provide efficiency and a maximum and optimum output with the least present expenditure and without any sapping of individual effort. In this Section we are concerned with the improvement of health as a whole, resulting from improved social conditions and material prosperity—especially of the wage-earning classes, but by no means confined to them—through many agencies, guided, instructed, inspired, often directed and even directly promoted by the machinery of national and local government, mainly through the officials of their public health services, and more particularly by their medical officers of health. As the first appointment of a medical officer of health was that made by the city of Liverpool in 1847, and appointments only became general under the Public Health Acts of 1872 and 1875, the progress of the public health movement may be said to be concerned mainly with the past half-century. Farr's *Vital Statistics*, dealing generally with conditions before 1870, may be taken as our guide to conditions before the public health movement set in, and the figures of the middle of the last century may be contrasted with those of the present day.

With these qualifications we may embark on our inquiry under the following headings:

Present:

1. What do sickness and disablement cost by loss of patients' work?
2. What do sickness and disablement cost in care and treatment?
3. What does it cost to maintain public health services?

Past:

4. What has been gained by the reduced number of deaths in sixty years?
5. What has been gained by increased expectation of life in sixty years?

Future:

6. What saving could be effected, as a single definite instance, by the elimination of tuberculosis?

1. What do Sickness and Disablement Cost by Loss of Patients' Work?

Let us consider the following figures:

Male members of approved societies in England and Wales = 8,637,095 (2nd Annual Report of Ministry of Health, 1920-21, pp. 153, 163).

Expenditure upon sickness and disablement benefit among men = £4,771,702 (Annual Report of the Chief M.O. of the Ministry of Health for 1920, p. 19); this represents an average minimum of incapacitation for 8,916,059 weeks, which is equal to the loss of a year's work of 178,280 men, or 2 per cent. of the insured male population.

Now the insured men number nearly one-fourth of the population, and there is further loss for which benefit would not be claimed. Therefore the total sickness and disablement of the whole population corresponds to a permanently sick or disabled population of, say, five times 178,280 = 891,400.

A somewhat similar result may be obtained in another way. Farr concluded that the total number of sick at any time throughout the year was about double the number of deaths occurring during the year. The number of deaths in England and Wales in 1920 was 466,213, and the number of sick and disabled would therefore be 932,426.

These two estimates approximate to one another, and suggest that 2½ per cent. of the population are on an average incapacitated by sickness and disablement. Production would thus be reduced by sickness and disablement to the extent of 2½ per cent.

(a) What does this signify to the Exchequer? The Exchequer receipts from personal services and production, excluding the return from capital, may be put on a conservative estimate at £100,000,000, and the loss to the Exchequer,

therefore, from the incapacity of those sick and disabled equals 2½ per cent. of this figure, or £2,500,000 per annum.

(b) What is the loss from sickness and disablement to the national income? Estimates of the national income vary between three and four thousand million pounds. Accepting the lower figure, and taking one-third of it as representing the yield of capital, we arrive at the national income from personal services as £2,000,000,000 per annum, and the loss to the national income, therefore, from the incapacity of those sick and disabled is 2½ per cent. of this figure, or £50,000,000 per annum. To this should be added, if we could estimate it, a very large loss from minor incapacity and from the lowering of health and moral from minor or temporary or incipient conditions of sickness and disablement.

2. What do Sickness and Disablement Cost in Care and Treatment?

The number of sick and disabled has been reckoned above as 932,426; of these the number in certain institutions is given in the census of 1911 as 434,843; the others are mainly being treated at home, and will number 497,583.

(a) In Institutions.—The number of patients and staff in work-houses, asylums, and hospitals (census 1911) = 506,723; of this number the staff = 71,880 and patients = 434,843. The cost of maintenance of the above institutions, at an average of £100 a year per head, would be roughly £50,000,000.

(b) At Home.—The number incapacitated, as estimated above = 497,583.

Number of doctors, subordinate medical service and nurses, by census.....	123,400
Number of chemists and druggists	60,851
Number of surgical instrument makers.....	9,155
Total.....	193,406
Deduct staff in institutions	71,880

Number professionally engaged in attending on home sick

121,526

To that figure of 121,526 should be added the number of attendants and those engaged in auxiliary occupations (other than doctors, nurses, etc., shown above), and we may therefore estimate that the number concerned with the care of the home sick is as high as 200,000.

Cost of these (at £120 per annum)	= £24,000,000
Add maintenance of home sick (at £70 per annum)	= £35,000,000
(a) and (b) Total (£50,000,000 plus £24,000,000 plus £35,000,000)	= £109,000,000

But to this figure must be added the indirect effect of epidemics on industry, which at a low estimate we may place at £11,000,000, thus bringing the total material cost in care and treatment to £120,000,000. From this, however, should be deducted the cost of living of non-adults below 20, which is taken roughly as the beginning of the productive period of life, as such cost would in the main be a charge on the community also in health. If cost of living account for one-half of the cost of maintenance, one-third of which is in respect of persons under 20 years of age, then this deduction amounts to one-sixth of £120,000,000, or £20,000,000. The net cost, then, of care of treatment of the sick and disabled may be estimated at £100,000,000.

1 and 2. Total Loss from Sickness and Disablement to the national income from already reckoned at £50,000,000 the community in England and is then £150,000,000.

This is of necessity but a rough estimate, but it is a minimum. Certain omissions, definite but difficult of estimation, have already been noted. Another very large omission is that of work lost to the community by the 71,880 staff of institutions and by the 200,000 persons engaged in professional and occupational attendance on sickness at home who would otherwise be free for productive work. The cost of maintenance and the loss of productivity of relations and friends attending on the sick have also been omitted. Such charges would not for some years be set free in case sickness and disablement could be eliminated from the community. But they figure largely among the expenses of the Sick Account.

3. What does it Cost to Maintain the Public Health Services (Water, Drainage, Sanitation, and the Like)?

This is a matter which we can hardly bring into our public health budget; but the following figures, taken from the second Annual Report of the Ministry of Health (p. 204), are suggestive:

*Expenditure of Local Authorities in England and Wales
(other than out of loans).*

Public health:	£
Sewers and sewage disposal	6,183,101
Collection and disposal of house refuse	4,583,566
Hospitals, sanatoriums, dispensaries, etc.—	
For tuberculosis	1,310,698
For venereal diseases	218,251
For other diseases	2,241,668
Maternity and child welfare	687,180
Baths, washhouses, etc.	1,122,134
Parks and open spaces	1,728,616
Vaccination	120,578—18,191,892
Lunatics and lunatic asylums	5,476,637
Mental deficiency	183,995
Housing of the working classes	1,072,488
Relief of the poor (excluding maintenance of lunatics in county and borough asylums)	14,863,024
Cemeteries	997,506
Waterworks	11,291,242
	£52,076,784

It is impossible to say what proportion of these services is debitable to public health, still less what proportion could be diminished if preventable diseases were prevented and, so far as possible, exterminated. Moreover, the expenditure on these matters from the public purse is inextricably mixed with expenditure from private sources—as, for instance, house construction and drainage, or in improvement of the food supplies. But it is this expenditure which must be set on the debit side of the account to be contrasted with the material value of the improved public health on the credit side.

4. What has been Gained by Reduced Number of Deaths in Sixty Years?

Let us for the sake of suggestion give the following figures taken from Sir George Newman's *Outline of the Practice of Preventive Medicine*, an official memorandum addressed to the Minister of Health and published in 1919 for 6d., and from the Registrar-General's quarterly return No. 292 dated January 31st, 1922.

	England and Wales.		London.	
	Death Rate.	Infant Mortality.	Death Rate.	Infant Mortality.
1851-60 ("the fifties") ...	22.2	154	23.7	155
1911-18 (63 years later) ..	14.8	105	15.5	106
1921	12.1	83	12.4	80

Compare (1921):

	Death Rate.	Infant Mortality.
Bombay	54.7	?
Madras	33.8	281
Vijenna	15.3	146
Paris	14.8	95
Berlin	12.4	135
New York	11.2	71
Amsterdam	10.3	54

Comparing, then, the deaths at the earlier period with those sixty years later (for these purposes the mortality in England and Wales 1847-50 is compared with that of 1901-10) the mortality rate in the first period applied to the population of the second period would have given 887,083 deaths; but the actual recorded deaths averaged in a year 575,515; therefore the number of lives saved yearly was 311,568. Of this number over one-third (namely, 119,377) lives were saved owing to the decline in mortality from small-pox, typhus, enteric fever, cholera, and diarrhoeal diseases—a reduction mainly due to sanitation.

Now these lives have a definite value, and I would ask the political economists to give me a good estimate for such value. The best figures I have been able to find are those provided by Sir J. Kay-Shuttleworth's "Return of wages of the best class of labourers in Norfolk,"* presumably in the middle of the last century, quoted under the heading "Value of a man's services" in Farr's *Vital Statistics*, p. 534.

* His life has been recorded in the *Return of Wages of the Best Class of Labourers in Norfolk*, K.C.S.I., and published by Murray, First Secretary of the E. national system of contact with the social problems of his day; for, first as a physician in

At the age of 25, comparing professional men on moderate incomes with agricultural labourers, the following figures are given as the value lost by an individual death:

	Professions on Moderate Incomes.	Agricultural Labourers.	
		High Scale.	Low Scale.
Future earnings	£ 10,462	£ 1,668	£ 795
Present value of future earnings at 3 per cent.	5,329	627	481

Kay-Shuttleworth calculated that at the age of 20, on a 5 per cent. basis, the prospective value of an agricultural labourer in Norfolk was £482; but from that figure should be deducted the amount required for necessary maintenance (£248)—giving the net value of his future services to the community £234. Supposing, then, we say that the labourer of Norfolk dying at the age of 20 (at the far lower value of his services sixty years ago than that of the present time) is over the average figure of present-day value for all lives lost, and taking such average to be £200, then the reduction of the last sixty years (311,568 deaths every year) is equal to a saving of £62,313,600 per annum.

Again I say that this is only a rough estimate of the value of the lives that have actually been saved. I hope political economists will compute this figure correctly. But that the lives saved have a value approaching the enormous figure given above, and that this saving is a result of the improved conditions of life and attention to health, is a fact.

5. What has been Gained by Increased Expectation of Life?

Another way of estimating the effect in improvement of health has been by calculating from life tables the increased expectancy of life. Comparing the life tables compiled respectively by Farr for the years 1838-44 and by King for the years 1910-12 (giving a contrast of seventy years), we find that

The mean after-lifetime of males aged 20 in 1838-44 was	40.0
and that The mean after-lifetime of males aged 20 in 1910-12 was	44.2

Therefore the age of productive labour was increased in seventy years by over 10 per cent. As we have already seen that the national income from personal services at a conservative estimate is reckoned at £2,000,000,000 a year, the saving by increased age of productive labour during these seventy years amounts to £200,000,000 a year.

Moreover, a larger proportion of children born reach the productive age. In the earlier period out of every million males born 653,357 attained the age of 20 years; but in the latter period out of every million males born 793,435 attained the age of 20 years, so that in the later stage for every million born 140,078 more reached the productive age, and the community expends so much less a head relatively on the unremunerative period of life.

6. For the Future what Saving can be Effected, as a Single Definite Instance, by the Elimination of Tuberculosis?

Tuberculosis is one definite cause of sickness which gives us definite figures on which to base a financial inquiry. Whether the total extinction of tuberculosis mortality is within the realms of possibility is immaterial to this calculation; but it may be observed that the average tuberculosis mortality for the years 1881 to 1885 was twice as heavy as that of 1919. The extinction of tuberculosis would thus, at the present time, mean no more than a reduction equivalent to that which has already taken place. Moreover, the 1920 mortality rate from tuberculosis was over 10 per cent. below the 1919 mortality from the same cause, and may be considered as a 10 per cent. instalment of total extinction. Had, then, the 1919 death rate been reduced by an extent equivalent to the 1919 mortality from tuberculosis, it is shown in life table form that within the productive ages 16 to 65 the

* See Law Commissioner in East knowledge of the urban and

years of life actually lived would have been increased by 4.7 per cent. Production in the year in question could therefore have been increased 4.7 per cent.; the increase in the Exchequer receipts from taxation (on the most conservative estimate of £100,000,000) would, it might fairly be assumed, have been increased by £4,700,000, and the national income of £2,000,000,000 from personal services by £94,000,000.

But, furthermore, tubercle affects more especially the productive ages of life. Assuming that production is limited to the ages 16 to 65 and that all other ages are dependent, the elimination of the 1919 mortality from tuberculosis would increase the productive years of life by 0.48 per cent. more than it would increase the unproductive years. For with the 1919 mortality from all causes there were by the life tables 64.47 years of productive life to maintain a hundred years of life; and in case of the extinction of tubercle there would be 64.78 productive years of life to maintain a hundred years of life. The difference is 0.31 year of life, which is a percentage increase of 0.48. The following argument is then suggested to me from a distinguished quarter. Taking the conservative figure of £2,000,000,000 as the national income from personal services, excluding return from capital, it is suggested that the extinction of tuberculosis would add a further sum of £9,600,000 annually to the national income. Capitalized at 5 per cent., assuming that the above percentage surplus of 0.48 accumulated as capital, this would be worth £192,000,000. I pass on this suggestion for what it is worth and invite correction.

The subject has been worked out very thoroughly in the United States of America, and it is there estimated that at the age of 20 tuberculosis reduces the expectation of life for the whole population of the registration States by 2.4 years. Economists calculate that for the whole population of the United States each year of life expectancy lost is equal on the average to a net loss of £20 to the national wealth. On account of tuberculosis, therefore, each person is worth approximately £50 less to the national wealth, and the State loss is (on 1911-16 population of 106 millions) £5,300,000,000, or (as average lifetime in the United States is fifty years) £100,000,000 per annum from tuberculosis alone.

Conclusion.

It will be seen, then, that the ascertainable cost of sickness and disablement to the community in England and Wales amounts to no less than £150,000,000 per annum. To this should be added large sums which I have been unable to express in financial terms. Judging from the estimate of £94,000,000 a year as the loss from tubercle alone, the estimated loss of £150,000,000 from all forms of sickness would seem to be grossly underestimated.

It will be seen that the public health services cost many millions a year. It will also be seen that during the course of the public health movement in the past sixty years the improvement in health has given a very large possible increase in output, which, reckoned on the basis of lives saved and the average wages of an agricultural labourer sixty years ago, works out at £62,000,000 a year; but reckoned from the increased expectation of life amounts to £200,000,000 a year—several times more than the amount spent on maintaining the public health services.

It is not claimed that all the loss to the community from sickness and disablement could ever be abolished, nor the services of public health be materially, if at all, diminished; but as in the past sixty years, so now, a large amount of sickness and disablement is still preventable.

In America, where this subject has been explored more thoroughly than in this country or, so far as I know, in any other, it is estimated that sickness and death in the United States, with a population about three times as great as that of England and Wales, cost £600,000,000 per annum, of which at least one-third is regarded as preventable. The ratio of preventability is defined as "the fraction of all deaths which would be postponed if knowledge now existing in well-informed men in the medical profession were actually applied in a reasonable way and to a reasonable extent."

As an instance of what may reasonably be expected in the prevention of sickness in the near future, we have taken the possible elimination of tuberculosis and shown such elimination should add £4,700,000 yearly to the Exchequer and £94,000,000 yearly to the national income. It is obvious, therefore, that any effective measures that have yet been proposed for the reduction of tuberculosis would be financially justified if consideration be merely confined to the material profit and loss to the Exchequer.

Stress must, however, be laid on the epithet "effective." Many measures put forward in perfect good faith by experts and by the public are not yet sufficiently substantiated to merit their adoption as "effective." Many are advocated too much from the standpoint of those who seek to raise the material comfort of the workers out of the Exchequer. While improvement of feeding and of other social conditions may be expected to diminish tuberculosis and improve health, it might have a precisely contrary effect if the method adopted were to undermine initiative, moral, and personal care of the individual. It is imperative for medical officers of health and for the medical profession generally, as expert guardians of the public welfare, to stand between the public and the Government; to recommend to the latter only such measures as can be proved to have value, and, in putting forward suggestions and hypotheses to be most careful in stating the limiting conditions.

With these reminders I beg confidently to recommend a serious study of the subject (of which the present paper is only a preface) to the attention of this Section, of the whole medical profession, and of the nation at large.

Acknowledgement is due more especially to Dr. W. H. Hamer, Medical Officer of the London County Council, for notes which he furnished to me on the subject, and to others who have helped me with information.

Amongst the articles and papers used in the preparation of this paper are:

Vital Statistics, by Dr. W. Farr.

Public Health and Insurance, by Sir A. Newsome, 1920.

"The Economics of Health," by Dr. James Niven (address to the Manchester and Salford Sanitary Association, April 25th, 1932).

"The Cost of Disease," by Dr. James Niven (being a paper read before the Manchester Statistical Society, March 8th, 1911).

The Economic Advisability of Inaugurating a National Department of Health, by J. Pease Norton, Ph.D. (Chicago Press of the American Medical Association, 1906); and

"Report on National Vitality, Its Waste and Conservation," by Professor Irving Fisher, of Yale University, (Bulletin No. 30 of the Committee of 100 on National Health. Washington: Government Printing Office, 1909.)

DISCUSSION.

Dr. MACFADYEN (M.O.H. Letchworth) said that this kind of research would be excellent, but should be worked out first for a large city like Glasgow. He admired the work of Dr. Chalmers in this city, but was convinced that, though excellent, it had gone beyond the point when it was economical—in other words, Glasgow was too big and should be divided up. The cost of public health from a national point of view could not be divorced from the cost of police and Poor Law.

Dr. HERBERT JONES disagreed absolutely with Dr. Macfadyen that too much was being spent on public health services. It would be found, if the amount were expressed in proportion to rateable value, that extraordinarily little was being spent, and in all probability the expenditure in the garden city of Letchworth, when so expressed, was as great as that in Glasgow when the difference in the municipal enterprises were considered. In rural districts the cost was rarely above an amount equal to a penny rate, and though in towns it might be much higher, even then, when so expressed, it was not alarming. Expenditure on public health measures, instead of being reduced, should be increased.

Dr. MILLER (C.M.O. Radnor) thought it desirable that proper units for public health administration should be formed with a population of about 50,000 and of suitable area. The burden of providing proper water supplies and efficient sewerage systems for small urban and rural areas would be eased and simplified by combination. Improvement in health and increased expectation of life should be accompanied by greater output of work per person.

Dr. A. K. CHALMERS (M.O.H. Glasgow) stated that so far as Glasgow was concerned the cost of public health works had risen from pence to shillings per head, but the death rate had been halved. Before comparing one place with another the kind and extent of the work done should be taken into consideration.

Dr. FREMANTLE, in reply, emphasized the fact that his paper was merely meant to introduce the subject and to encourage others to look at public health work from a standpoint which had not hitherto received much attention.

INTERPRETATION OF THE DEATH STATISTICS OF INFANCY AND CHILDHOOD IN RELATION TO DEVELOPMENT AND ENVIRONMENT.

BY
JOHN BROWNLEE, M.D., D.Sc.,

Director of Statistics, Medical Research Council.

THE result of environment upon child life is an exceedingly complex subject. I would like to-day to direct attention to some of the main conclusions which can be drawn from the statistical side and to point out the relations these may have to the problems of administration.

The chief branch of the subject I wish to discuss is one which has specially interested me—namely, the manner in which the death statistics throw light upon the physiological changes which take place in the developing child. From conception onwards the physiological processes in childhood have certain obvious divisions, but there are others which are not so easily observable. The first of these is ante-natal. The second is the short period of actual birth with some few succeeding days. These are definite and easily recognized. But with birth a number of other risks are present. With their sudden change of environment the respiratory, digestive, and nervous systems have new and special work thrown on them. These changes are associated with very special dangers, dangers which must be still greater when the birth is premature. There is thus a very high mortality in the first month of life which rapidly declines. There is, however, a third group of changes which are truly developmental. Thus we find during the first year of life periods at which digestive and lung diseases are specially frequent, while with some of the specific fevers the highest rate of mortality may occur as late as the fourth year. These points will be discussed in detail.

The first period of life is the parasitic period in the uterus. In this period, to my mind, heredity plays the main part, and there is very little statistical evidence that the environment in which the mother lives produces much immediate effect. Thus the infantile death rate in the rural counties in the first month of life, as given by the Registrar-General for England, is very little different from that in the urban counties, the figures being respectively 36.9 and 39.9 per thousand births—an increase of 8 per cent., while the increase of the urban over the rural infantile death rate under one year for all causes is 30 per cent (see Table I). The figures published by the medical

TABLE I.—Showing the Death Rates per 1,000 Living Births among Infants during the First Twelve Months of Life in the Urban and Rural Registration Counties from Infantile Diseases and Diseases due to Infection.

Infantile Diseases.—Premature birth; congenital defects; starvation; rickets; injury at birth; convulsions;

Diseases due to Infection.—Measles; scarlet fever; diphtheria; whooping-cough; enteric fever; gastro-intestinal catarrh; diarrhoea; tuberculosis; tonsillitis; other tuberculous peritonitis; rickets; meningitis; laryngitis, catarrh; gastritis; gastric

officer of health for Brighton, Dr. D. Forbes, show that only when the best class of house is reached is any special difference found; below this level the death rate is practically constant. Some figures collected by Dr. Findlay and Miss Agnew relating to Glasgow (in process of publication) show the same thing. The environment, therefore, of the mother during pregnancy is not of such great importance to the immediate welfare of the child as might be supposed. I do not of course maintain that there is no advantage to the child afforded by ante-natal care of the mother. Ante-natal care will probably diminish abortion and will undoubtedly save the lives of a certain number of children. The amount of saving, however, cannot in any case be very large. There is, apparently, for every thousand children born about thirty stillbirths, and of these Dr. Holland estimates that with better midwifery and with ante-natal treatment a half may perhaps be saved.

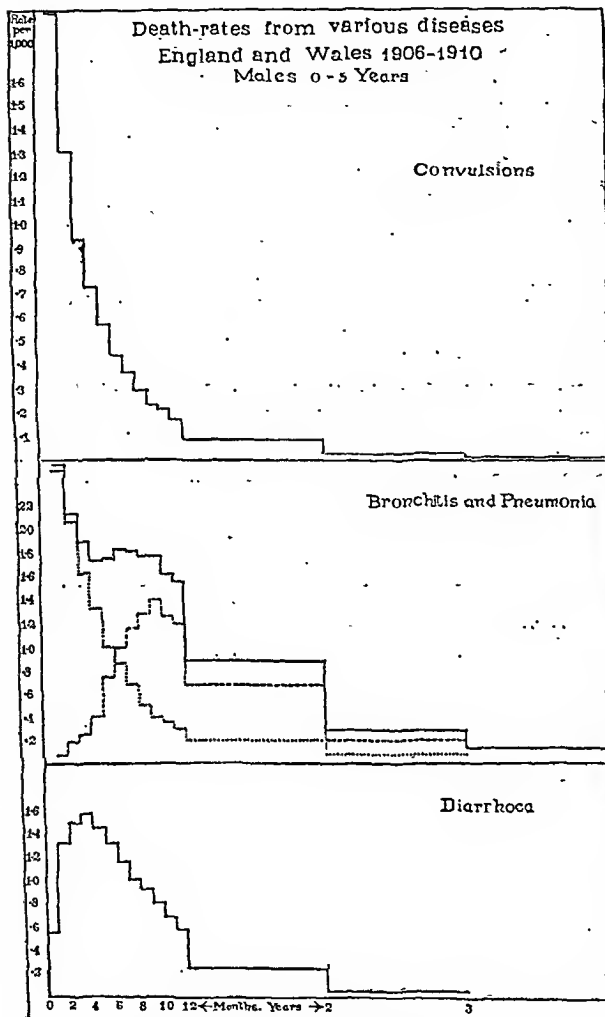

What is important to the child is its own environment after birth, and if that of the mother be bad the child's will be equally so. If the environment is good the recuperative force in a child born of parents of good stock is such that even when during the late months of pregnancy the nutrition of the child is bad, this is very generally rapidly restored after birth. The influence of the health of the mother upon the health of the child after birth, however, stands in a different category. The child is dependent for its growth upon healthy food, and an unhealthy mother is in most cases quite unable to produce milk in amount and quality required for the child's upbringing, with the result that artificial feeding must be adopted, and with artificial feeding the chances of alimentary disturbances are considerably increased. It is in this direction that it would seem that ante-natal care of the mother will be of the greatest importance.

Passing now to the act of birth, the child as it is being born is seen to be subjected to intense strains—strains in many cases sufficient to produce death, and in many other cases disturbances such as are not recovered from for some weeks or months; but these conditions, the result of trauma, do not concern us here. What does concern us is the change of environment which takes place as regards the child. The system which is first involved is the respiratory, the method for the provision of oxygen for the physiological processes being suddenly and almost in an instant changed. The change alone is sufficient in a number of cases to produce death, the heart of the child acting at birth, but respiration never becoming established, though this is commonly associated with cerebral injury.

In association with this there is the change in nutrition, the infant having to digest its own food. In many cases the response to the stimulus of food fails and the child dies of atrophy or inanition.

Much more interesting, however, are the changes which take place after birth. These changes may perhaps be best understood first by taking two typical examples. The first type, which may be called the true infantile mortality, decreases very rapidly after birth. Of this the best example is the course of the death rates ascribed to convulsions without predisposing cause. The death rates are illustrated in the diagram, in which the first entry refers to the second month of life, the death rate from convulsions in the first month being so great that it cannot be inserted. The progress of the fall in the death rate is perfectly regular. It is not only possible to graduate the death rates at each month under one year to a suitable mathematical curve, but when the curve has been fitted to these values of the death rates it is possible to predict the number of deaths in the next three years of life with very great accuracy. It can therefore be taken that the gain in stability of the nervous system with growth in the average child is regular and governed by very definite laws. These laws are fundamentally powerful, for it may be observed that there is no evidence that the period at which teething commences affects the number of deaths. What causes convulsions is of course not known. It must be related to an instability in the nervous system on which many different disturbances of health produce the same result. The whole environmental risks of the child, therefore, must be taken as acting on a nervous complex, but the factor which determines the likelihood of death at each age is to be found in the condition of the nervous system as it passes from instability to stability. It is further to be noted that the occurrence of convulsions is to a very great extent independent of hygienic environment, the children in the rural districts having an almost identical death rate at

each age from convulsions with that of the urban districts; the death rate under one year in the urban districts being 11.19, and in the rural districts 11.04. The above remarks are confined to deaths from convulsions when this is given as the chief cause of death. Deaths from convulsions in the ordinary summer diarrhoea or the ordinary pneumonia of childhood—causes given as the primary cause of death—appear under the heading of the primary cause and not under the heading of convulsions. Were this not the case, it is hardly probable that the progress from age to age would be so regular.

As convulsions may be taken as the type of one physiological change, so diarrhoeal diseases may be taken as a second type. The course of the death rate from diarrhoea is illustrated in the diagram. Here we find that ordinary diarrhoeal diseases are not common in the first month of life, but after the first month death becomes more and more common until the fourth month is reached, after which the decline in the death rate is slower and slower. In this case it is again possible to take the death rates under one year of life, fit them to a mathematical expression, and predict the death rate for the next two years of life. Here again we must have some cause determining the rate of change, a change shown by the different response of the child to this type of infection. It may be regarded in the light that in the growing child during the development of the digestive system some substance or condition of the alimentary tract which tends to instability is produced, and that the causes which lead to this instability are in their turn removed so that the digestive system resumes its stable condition. Another common abdominal disease of childhood, tuberculous peritonitis, also shows a similar course in the death rate. In tuberculous peritonitis, however, the maximum death rate is about a fortnight to

three weeks later than in the case of diarrhoea, as is to be expected on account of the more chronic nature of the disease.

The changes which take place in the lungs, as shown by the presence of respiratory disease, fall next to be discussed. The two chief diseases are bronchitis and pneumonia, and in the young child there is a great clinical difficulty in differentiating them. At the present moment the pathology of this subject is in a very unsatisfactory state. Even when by clinical observation the diagnosis seems to be quite clearly bronchitis, microscopical examination may record more or less extensive alveolar infection. The course of the death rate from the combined respiratory diseases is shown in the diagram. There is a fall during the first few months of life, followed by a rise. Here a level is kept for a considerable time, to the end of the first year, and (if the statistics were available) probably for a few months into the second year. A marked hump like this on the curve of the death rate seems always to be due to a mixture of diseases. In the separate certifications bronchitis appears much more in the earlier months of the first year, pneumonia in the later months. I do not think, however, the certificates of death differentiate to the extent that might be possible. What has been done, therefore, is to take the death rates as they stand and make a rough analysis into two types of diseases, one of which—bronchitis—is a true infantile disease, the death rate from which decreases steadily from birth, and the second a disease in which the death rate rises to a maximum about the ninth or tenth month of life and thereafter declines. During development in the first two months of life elements causing instability predisposing to bronchitis pass away, possibly simply by the growth in the size of the tubes of the respiratory apparatus permitting mechanical cleansing more readily, but also possibly associated with the increasing local immunity of the mucous membrane enabling it to withstand infection. On the other hand, pneumonia, from being a less common cause of certification of death in the early months, rises to a maximum in the eighth and ninth months and thereafter declines. In the growth of the lung, therefore, there is a period during which a temporary instability appears, much the same as in the digestive system there is a period followed by the growth of a greater and greater power of resistance. On this interpretation an analysis of the combined cases of respiratory disease shown in the diagram has been made. Bronchitis is shown by a dotted line and pneumonia by a line of dashes, the sum making the combined graph of bronchitis and pneumonia and showing how the large hump on the graph in the latter months of the first year is to be explained. As regards the infective agent, it is natural at first to think that one class of organism will produce bronchitis and another pneumonia, but this is not necessary. If there be two kinds of instability—an instability which gradually disappears and an instability that develops—it is, I think, quite possible that the same cause might produce both bronchitis and pneumonia and also account for the fact that it is very difficult to differentiate the two diseases. But that there are two diseases, in the sense of two responses to irritation, I have no doubt. This is made certain when the death rate from pneumonia, as given by the analysis, is compared with that of measles. If the curves of these death rates are placed above one another they are almost identical. During the early months of life death from measles is exceedingly uncommon, but it begins to be more common at the fifth month, has its maximum about the twelfth month, and remains high during the first year of life, thereafter decreasing very markedly. Now deaths from measles in young children are nearly always associated with that suffocative catarrh which occurs when the rash appears in the lungs, and which in many cases, if the children do not die at that stage, passes into bronchopneumonia.

All the other diseases of infancy come into one or other of these two classes with the exception of some of the specific fevers. With these diseases there is a quite definite increase of susceptibility with age, the maximum susceptibility to scarlet fever occurring apparently between the ages of 5 and 6 years; to diphtheria between the ages of 4 and 5 years; and to whooping-cough between the ages of 2 and 4 years. It is to be noted, however, that in all these diseases the mortality steadily declines though the susceptibility increases.

The importance of the phenomena just shown lies in the light they throw on some questions of immunity. It is commonly stated that children continually receive small infections of different kinds and thus develop immunity. In this manner

the age variation of susceptibility to disease is explained. In one case, fortunately, the case of summer diarrhoea, this can be completely eliminated. The incidence of the disease is here practically confined to two months in the summer, so that children of all ages under one year of age are exposed for the first time to infection during a narrow interval. The course of the death rate, therefore, must be associated with something else than the child's acquired immunity, and it seems practically certain that the susceptibility to death is due to some physiological condition in the individual. Another explanation offered to account for the smaller number of deaths from diarrhoea under the age of four months is that more children are being fed on the breast at the earlier ages; this also seems to me to be difficult to accept, since the progress of the susceptibility to death from age to age can be so uniformly graduated, the graduation describing not only the death rate under one year but permitting prediction of the death rate for the two following years of life. Taking, again, the deaths from convulsions, where the death rate follows just as rigid a course—that the cause must be sought in the physiological development of the child is strongly suggested.

TABLE II.—Mean Infantile Mortality in Groups of Registration Districts, with the Actual Mortality between 2 and 3 Years of Age and a Calculated Mortality, if the Mortality at the latter Age Rose Correspondingly to the Infantile Mortality.

MALES.			FEMALES.		
Mean Infantile Mortality.	Mortality 2 to 3 Years.		Mean Infantile Mortality.	Mortality 2 to 3 Years.	
	Actual.	Theoretical.		Actual.	Theoretical.
84	9.7	8.9	76	9.5	8.9
96	8.8	9.8	85	10.0	9.9
105	10.4	10.4	95	10.9	11.0
115	10.7	11.2	105	12.0	12.1
125	11.8	11.9	114	13.1	13.1
135	12.8	12.7	124	16.2	14.2
144	14.3	13.3	131	17.5	15.4
154	15.0	14.1	145	20.5	16.6
165	18.4	14.9	155	23.5	17.7
175	21.7	15.7	163	25.3	18.6
185	23.9	16.4	175	25.0	19.9
191	26.3	17.1	186	32.2	21.2
201	25.7	17.3	192	31.9	21.8
214	29.4	18.6	205	38.3	23.3
225	26.7	19.4			
237	40.4	20.3			

The chief infectious diseases of children—namely, whooping-cough, diphtheria, and scarlet fever—however, also offer some information. In these diseases up to a definite age the child becomes gradually more susceptible to the disease while at the same time it becomes much less susceptible to death. On the immunity hypothesis just described, frequent small infections must thus tend to render the child more susceptible to an attack of the disease but less susceptible to a fatal attack. The decay in the death rate, however, is described by the terms of a geometrical progression. This suggests a law of its own quite independent of the variation of susceptibility. The whole of the general argument of small doses producing immunity seems to me to be insecurely founded, and in one instance it can be definitely proved wrong. With small-pox an increasing immunity to the disease develops after the age of 15 years, and there is in this case no question of small immunizing doses being constantly present. The only case in which anything approaching experimental verification of the theory exists is that of diphtheria.

Having thus noted the physiological changes which take place, a further question remains to be investigated—namely, the progressive effect of an unhealthy environment on the development of a child. The usual measure of the effect of

environment on child life is called the infantile mortality, which is the number of deaths out of each thousand births. All such measures are open to some statistical objection, but this measure is as good as any other and may be taken as a criterion. Taking this, then, as a criterion and arranging the registration districts in England and Wales in groups according to the order of the infantile mortality, and comparing the infantile mortalities of those groups with the mortalities in the following years of life, the progressive effect of an unhealthy environment may to some extent be estimated. It is found that, with each increment to the infantile mortality, the increment of the mortality in the second year of life is greater than the infantile mortality would lead you to expect. In mathematical language, a term in the square of the infantile mortality must be added. During this period, therefore, there is progressive deterioration in the child's life. The excess of the real values over proportionate values is shown in the accompanying table (Table II). The greatest effect seems to be about the age of 1.8 years. When the succeeding years of life are examined the difference becomes less marked, the factor multiplying the second power of the infantile mortality halving itself with each year of life until, when the age of 4 to 5 years is reached, increments in the mortalities are very nearly directly equivalent to increments in the infantile mortality. Whether this represents a gradual stiffening of resistance to disease with growth or whether it represents survival of the fittest is a matter on which it is difficult to express an opinion.

Dr. J. C. McVAIL, in thanking and congratulating Dr. Brownlee for his paper, remarked that the author was in the singularly fortunate position of being at once a medical man and a mathematician, a rather rare combination. He would not venture to criticize or even discuss the paper, for it was one to read and study carefully.

PUERPERAL MORTALITY IN SCOTLAND.

BY

T. F. DEWAR, C.B., M.D., D.Sc. (PUB. HEALTH) EDIN.,
Medical Officer, Scottish Board of Health.

MATERNAL mortality may be expressed in terms of maternal deaths per 1,000 persons living; more usefully in terms of maternal deaths per 1,000 women of child-bearing age—conventionally reckoned as from 15 to 45; but best and most accurately and conveniently of all, in terms of maternal deaths per 1,000 living births or 1,000 births of viable children. To secure accuracy for purposes of comparison, it is necessary to define the term "maternal deaths"; that term must obviously include deaths of all natures, alike those that have a definite connexion with child-bearing and those that have only a presumptive association therewith or none at all; and it must be arbitrarily restricted on the one hand to deaths occurring after a certain stage of pregnancy, and, on the other, to those occurring within a certain number of days after delivery. The former period may be put at seven months, the latter at twenty-eight days. This interval of four weeks has the advantage over the period of thirty days that the days of the week are an assistance to the memory; for example, if delivery takes place on a Monday, the period after which death ceases to be reckoned as "maternal" ends on a Monday also.

It is clear that these time limits secure uniformity for purposes of fair comparison at the cost of artificial and arbitrary distinctions. It is true that a certain proportion of deaths associated directly with the puerperal state will not ensue until more than four weeks have elapsed after delivery; but it is also the case that a number of maternal deaths occurring within twenty-eight days after delivery will have no essential association but merely a coincidental connexion with the fact of motherhood.

Fair comparison between the puerperal death rates in various countries or at various times can only be made if the method of expressing that death rate is the same in each case. There is reason to fear that this uniformity of method has not been achieved.

Further, comparative statements of puerperal mortality according to the specific nature of the cause of death can be reliably made only if every possible source of fallacy has been excluded. On first thought it may seem that the group of

septic puerperal deaths might be defined with some ease and precision; but reflection shows that typical puerperal septicaemia, a septic pneumonia in the puerperal period, a septic condition of remote origin (that is to say, local origin not connected with the organs of generation), an attack of acute infectious fever such as measles, or indeed of any pyrexial malady occurring at or soon after delivery or precipitating delivery—that these form a chain or series which it is not easy to sever artificially at any point.

With these reservations as to the inductions that may profitably and fairly be made from them, let me place before you some facts.

In the year 1919 the rate of puerperal mortality in England was greater than for any year since 1905—namely, 4.12 per 1,000 births. The regrettable pre-eminence of this rate over those of the previous thirteen years applied both to puerperal mortality as a whole and to the mortality from puerperal sepsis taken separately; indeed the increase of the whole puerperal mortality rate in 1919 as compared with that of previous years was preponderantly due to septic disease.

For the year 1920, in England, the total maternal mortality rate was the same as in the previous year, 4.12 per 1,000 births; but while the rate for deaths from "other accidents and maladies associated with maternity" fell from 2.36 to 2.25 per 1,000 births, the rate for septic maladies associated with maternity (including phlegmasia dolens) rose from 1.76 to 1.87 per 1,000 births. These figures the Chief Medical Officer of the Ministry of Health regards, not unnaturally, as extremely disquieting. In his annual report for 1920 he points out that in that year the number of notifications of puerperal fever in England was 2,898 and the deaths were 1,750, "which indicates either that the fatality was extremely high or, what is more likely, that the notifications did not represent the number of cases of puerperal fever which actually occurred"; and that the deaths from puerperal fever by no means represent all the evils for which it is responsible. The Chief Medical Officer's report states that "undoubtedly the solution of this grave situation is mainly dependent upon improved midwifery."

During the decade 1911-20, 6,913 deaths ascribed to diseases and accidents of pregnancy and parturition were registered in Scotland. Of these, 1,831—fully one-fourth—were certified as due to puerperal sepsis. The annual rates for each category per 1,000 births are shown in the following table:

Year.	Deaths from Puerperal Sepsis per 1,000 Births.	Deaths due to other Diseases and Accidents of Pregnancy and Parturition per 1,000 Births.	Year.	Deaths from Puerperal Sepsis per 1,000 Births.	Deaths due to other Diseases and Accidents of Pregnancy and Parturition per 1,000 Births.
1911	1.42	3.74	1916	1.69	4.03
1912	1.57	3.92	1917	1.72	4.26
1913	1.33	4.55	1918	1.15	5.85
1914	1.85	4.18	1919	1.41	4.80
1915	1.94	4.19	1920	1.77	4.36

From the above it may be seen that the death rate from puerperal sepsis in Scotland in three of the years of the last decade is higher than it was in England in any year of the same period save the last. Moreover, there is good reason to believe that in Scotland, at least, some of the deaths which might properly be certified as due to puerperal sepsis are so certified as to fall into the group of "other diseases and accidents of pregnancy and parturition."

In Glasgow the number of cases of puerperal fever notified in the years 1914-19, the proportion per 1,000 births, and the number of cases terminating fatally are as follows:

Year.	Cases Notified.	Proportion per 1,000 Births.	Total Cases.
1914	218	7.4	81
1915	188	6.7	73
1916	193	7.2	69
1917	164	6.8	51
1918	168	7.1	45
1919	182	7.0	53

From this table it appears that out of the total of 1,115 cases notified in the six years, 372, or almost precisely one-third, proved fatal. From this high case-mortality rate it is clear that, as a rule, only those cases that are of considerable gravity or threaten to have possibly a fatal issue are notified. But the

proportion of deaths to notifications (33.3 per cent.) is in satisfactory contrast to that previously quoted for England, where in 1920 the proportion of deaths to cases notified was fully 60 per cent.

In Glasgow for the five years ending 1919, the notified cases of puerperal fever were attended as follows:

By doctor	120
By midwife	189
By nurse and doctor	89
By institutional nurse	43
In institution	38
Others (including cases from outside the city)	21

No apportionment of blame can be based upon these or similar statistics, since (1) the total number of confinements in each class is not shown; (2) institutional cases may be and doubtlessly frequently are infected before admission to hospital; and (3) midwives unaided attend normal cases only, while doctors not only have in their own charge a larger proportion of difficult or abnormal cases than midwives have, but also render assistance to midwives in their difficulties. I am assured, however, that in special institutions such as maternity hospitals, where, of course, labour is attended with all due precautions as regards sepsis, it is rare or unknown for cases to develop puerperal sepsis unless opportunity of acquiring such infection had occurred prior to admission.

The Fourth Annual Report (for the year 1920) upon the Administration of the Midwives (Scotland) Act, 1915, in the Middle Ward District of the county of Lanark shows that 61 cases of puerperal sepsis were notified out of 7,562 births, or about 0.8 per cent.; 54 per cent. of these occurred among cases attended by medical practitioners. Cases of notified puerperal sepsis occurred in the practice of doctors at the rate of 8.3 per 1,000 births (one case per 121 births), in the practice of midwives at the rate of 7 per 1,000 births (one case per 143 births). These figures have to be interpreted in the light of the proviso already stated.

In Scotland, for the year 1919, as has been stated, the total death rate from puerperal conditions per 1,000 births was 6.21. That proportion is maintained with approximate equality in the various parts of the country.

For the larger burghs it is	6.4
For the smaller burghs it is	5.9
For the country districts it is	6.2

Among the cities and large burghs it ranged, in that year, from 4.6 in Paisley to 8.2 in Edinburgh. These figures deal with the total puerperal death rate; septic conditions accounted for 23 per cent. of the whole.

In a recent article (April, 1922) on the infant and maternal mortality in Montana, issued by the United States Public Health Service, wherein the maternal death rate is expressed in terms of the female population of child-bearing age (15-44), it is stated that for the four-year period 1910-13 and among eleven European countries the rate ranged from 29.3 deaths per 100,000 in Sweden and 32.0 in Norway, to 62.2 in Scotland and 63.8 in Belgium.

It is further stated that (expressing the rate in deaths per 1,000 births), in 1910, in fifteen foreign countries the highest rate recorded is from Scotland with 5.7, the lowest Italy with 2.4. (These figures are given primarily in order to furnish a basis of comparison with similar statistics for the State of Montana and the United States generally.)

It may be noted that in the United States, as here, septic conditions cause about one-fourth to one-third of all the deaths associated with the puerperal state.

In New Zealand, according to the official periodical of the Ministry of Health of that country, the mortality associated with childbirth and the diseases of pregnancy has remained high for several years and has recently been rising. The rate in 1920 was 6.48 per 1,000 live births. For the last quinquennium 36 per cent. of the average maternal mortality was due to puerperal infection. A committee specially appointed to deal with these alarming figures makes a number of recommendations, of which one is that "every case of maternal death shall forthwith be personally investigated by the medical officer of health, who shall report to the Director-General of Health"; and another that "every case of notified puerperal sepsis shall be forthwith personally investigated by the medical officer of health."

In the city of Aberdeen since the beginning of 1917 a full inquiry has been made, so far as practicable, regarding every death of a woman occurring within four weeks of confinement. During the five years in which such inquiry has been made, the total puerperal death rate and the septic puerperal death rate, per 1,000 births, have been respectively as follows:

Year.	Total puerperal death rate per 1,000 births.	Puerperal septic death rate per 1,000 births.
1917	9.8	2.7
1918	7.0	2.1
1919	6.7	0.3
1920	6.0	1.0
1921	6.0	1.4

From the annual report for the year 1920 of the Chief Medical Officer of the English Ministry of Health (already repeatedly referred to) it is learned that an investigation into the whole question of maternal mortality in England has been arranged for. In New Zealand, as I have mentioned, a commission was appointed to deal with the subject and has reported. It would seem that in this country of Scotland also inquiry regarding the causes of the high rate of maternal mortality, and the means of lowering it, might be desirable.

DISCUSSION.

Dr. HERBERT JONES regretted that Colonel Dowar had not expressed his own views as to the remedy for the deplorable conditions he had detailed. He had related what was being done in New Zealand, and had quoted Sir George Newman's dictum that "the solution of the situation was mainly dependent upon improved midwifery." But was that the case? We had had improved midwifery now a good many years, but not much lessening of puerperal sepsis. We were too apt to forget the importance of removing insanitary surroundings—providing water supplies to every house, removing manurial accumulations, etc. It could not be expected that the necessary standard of cleanliness could be achieved in cottages where every bucket of water required had to be carried 100 or 200 yards.

Dr. SHANNON (Maternity Hospital, Glasgow) said that he was of the opinion that incidence of sepsis would be reduced if every case was looked upon as a surgical operation and the same care exercised. He insisted on the better teaching of obstetrics and urged that longer time should be spent by the student in his training of midwifery from its clinical side. He deprecated the so frequent use of forceps and urged that nature should do its job. He thought all major cases of obstetrics should be treated in hospital or by the specialist.

Lieut.-Colonel F. E. FLEMING, M.B., M.P., Scotland, if any share in blame for the increased puerperal mortality should be attributed to sanitary conditions. Surgical operations were now done in most insanitary conditions, stress being laid on the need of personal asepsis and little on the sanitary character of surroundings. It might be suggested that the improvement first resulting from the operation of the Midwives Act was due to the use of antiseptics and to aseptic teaching, and that the recent change for the worse might be due to an increased practice of vaginal examination, owing to the increased knowledge by midwives and by the public of what could be learnt thereby. In any case he believed the personal element would best repay investigation as accountable for the increase in puerperal mortality.

Dr. PICKEN (M.O.H. Cardiff) drew attention to the importance of not unduly incriminating the midwife in this matter. The majority of cases appeared to occur among abnormal cases where medical practitioners found it necessary or advisable to adopt instrumental interference. In this disease home sanitation seemed to be of less importance than specific prevention by improved midwifery.

Dr. MORRIS (M.O.H. Neath) protested against laying the fault at the door of the medical practitioner. Thirty years ago maternal morbidity was extremely great. To-day it was almost non-existent. Midwifery practice was in need of improvement, but domestic sanitation was of less importance in its effect on incidence of septic infection. There was great need of improving the conditions of livelihood of midwives.

Dr. LEWIS-LLOYD (C.M.O. Merioneth) protested against the loose phraseology used in assigning blame to midwives or to doctors. The number of cases occurring in any area should be correlated with the number attended by doctors or midwives, alone or together.

NURSE BARKER (Inspector of Midwives, Glasgow) caused some amusement by stating that midwives often came to her "in tears" because of the injuries done by doctors in the inconsiderate use of forceps. She was of the opinion that more patience should be exercised and instruments resorted to less frequently in an unnecessary attempt to assist nature.

Dr. DEWAR, in reply, said that as a civil servant his mouth was sealed so far as suggesting a remedy, even if he knew one. The doctor in attendance might occasionally be guilty in a physical sense, but he was often the victim of circumstances. The whole subject was one that demanded close investigation.

DISCUSSION ON DEFECTS IN SCHOOL CHILDREN.

OPENING PAPER

ROBERT BRUCE, M.B., CH.B., GLAS., D.P.H., EDIN.,
Senior Assistant Medical Officer, Education Authority, Glasgow.

It is my intention, in the time at my disposal, to deal with the diseases affecting school children, more especially the 5-year-olds.

In the first place I shall draw your attention to the conditions disclosed by the routine medical inspection of entrants to our schools, and afterwards to the consideration of the conditions which produce crippling at school age. I use the word "crippling" in its widest sense, in fact to cover all conditions which so affect the health of the child as to prevent his being educated in the ordinary school. The figures which I shall give you are obtained from the results of routine examinations carried out during the session 1920-21, and also from the medical reports on those children found unfit for attendance at ordinary schools during the same period.

The total number of children on the register in the session 1920-21 was 198,282—the average attendance being 170,522, or 86 per cent.; 15,605 children were examined at the age of 5 (7,828 boys and 7,777 girls), and the conditions enumerated in the following table (p. 347) were disclosed.

These are the conditions found among the 5-year-old children attending ordinary schools. Let us now consider the conditions found amongst these children who for one reason or another are unfit to attend school. When the attendance officer finds that, owing to alleged disability, certain children have not been enrolled at any school he arranges for their examination, so that they may be allocated to special schools, or entirely exempted from school attendance if necessary. During the session 1920-21 out of a total of 1,252 children so examined 454 were 5 years old. Before proceeding to analyse the conditions found, I would explain that in the following cases, where two or more conditions are present in the same child, only the primary crippling cause is referred to; 454 children of 5 years of age were examined in this way, and the following conditions found:

Rickets	263=57.9%
Non-pulmonary tuberculosis: "bones and joints affected in 22, glands in 12, abdominal tuberculosis 5, skin infected in 2" ..	41=9.0%
Lung conditions: "chronic bronchitis 26, suspected phthisis 3, empyema 1" ..	30=6.6%
Mentally defective: "3 idiot and 26 imbecile—2 mongols and one a cretin" ..	29=6.3%
Nervous diseases: "infantile paralysis 13, hemiplegia 5, epilepsy 5, spastic paraplegia 2, chorea 1, neuroses 8" ..	34=7.4%
Anaemia and malnutrition	18=3.9%
Valvular heart disease: "5 congenital, 3 acquired" ..	8=1.7%
Eye diseases: "strabismus 9, congenital cataract 1" ..	10=2.2%
Congenital deformities	11=2.4%
Deformities the result of injury ..	4
Hernia	2
Osteomyelitis	2
Chronic eczema	1
Deaf-mute	1

Rickets.

From these figures there emerges, first of all, the striking fact that at 5 years of age 58 per cent. of the crippling found to exist in school children is due to rickets, and to rickets of the most pronounced type. The children affected are twisted and deformed, stunted in body, and retarded in mental development. Many of them are quite unable to walk, or even stand. After a few months in our special schools many of these children improve markedly in their general physical condition, feel fit and well, and for the most part can run about—a striking contrast to their helpless state at the time of admission. Unfortunately, however, their deformities remain, although in later years even these improve in varying degree.

Now, whatever may be your views on the causation of rickets whether you agree with Professor and Mrs. Mellanby that it is due to the deficiency of fat-soluble vitamins, or with Professor Noel Paton, Dr. Leonard Findlay, and other workers in the Glasgow School, that it owes its origin to lack of fresh air, sun light, and exercise, you will, I am sure, agree with me that there is something seriously wrong when a disease, which makes its appearance at such an early age and is so eminently curable, is still found in its acute form producing such an enormous percentage of the total crippling found at the age of entering school.

Over forty years ago my father, Dr. R. Wilson Bruce, who had an exceptionally large and unique experience of the condition: existing among children in Glasgow, both as medical officer to the school board of Glasgow and as medical superintendent of Eastpark Home for Infirm Children, came to the conclusion after observation of a large number of rachitic families, that the constant factors in the causation of rickets were overcrowding, hermetically sealed windows, and lack of sunlight—the mothers in the majority of cases being unable or unwilling, either because of weariness or laziness, to take the children out. Nowadays the education authority has powers to treat and feed all necessitous cases, and it may be somewhat difficult to decide how much of the rapid improvement noticed in rachitic children attending special schools is due to the feeding and cod-liver oil supplied, and how much to the superior hygienic conditions under which they spend a large part of their day. When I was first appointed medical officer in charge of the special schools under the former school board of Glasgow these powers did not exist, and in consequence children whose parents were unable or unwilling to pay for the feeding had to go without. Children suffering from rickets who were not receiving feeding nevertheless made marked progress towards recovery. The very fact of their being taken from their dark stuffy homes and brought into the bright, cheerful, well-ventilated schoolrooms had undoubtedly a curative effect. Another point which I have noticed is that once rachitic children have been fairly set on their feet by attendance at special schools, they very rarely relapse, although they return at once to ordinary schools and their old home and feeding conditions. This I attribute to the fact that once they are able to run about sufficiently well to climb up stairs to their three or four storied tenement houses, the children see to it themselves that they get plenty of fresh air and exercise.

While I do not for a moment doubt that prolonged lactation, defective dietary, and other debilitating influences play their part in the causation of rickets, I cannot help feeling that the reason that so much active rickets is present among school children at the age of 5 is that nothing short of early removal from their unhygienic overcrowded homes will be of any service in the prevention or curing of this disease. This measure I am afraid in the present state of the country's finances is out with the bounds of practical politics. These opinions have been greatly strengthened by the researches of Professor Noel Paton, Dr. Leonard Findlay, and others of the Glasgow School, and more recently by a paper on rickets in India read before the Royal Medico-Chirurgical Society of Glasgow by Dr. Harry Hutchison, in which he proves that in India rickets is only found among the wealthy purdah classes in spite of a plentiful dietary rich in vitamins, whereas among the poorer classes who practically live in the open air it does not exist.

Tuberculosis.

The next most frequent cause of crippling among 5-year-olds is tuberculosis, which is responsible for 9 per cent. of the total crippling. There is, of course, no doubt that the ideal treatment for these cases is prolonged residence under hygienic conditions in suitable sanatoriums, with plenty of fresh air and sunlight. Unfortunately in this part of the country the sunlight is a very variable quantity and we can hardly expect the brilliant results obtained at the Treloar Cripples' Hospital, Alton, Hants.

For many years in Glasgow there was, with the exception of the limited accommodation at Eastpark Home, no intermediate place between the general hospital and the special school for the prolonged treatment of surgical tuberculosis, but a short time ago the Corporation of Glasgow opened a large hospital at Robroyston where these cases can undergo treatment for long periods under the best hygienic conditions. Arrangements have been made in conjunction with the medical officer of health for the education of school children in Robroyston Hospital.

If we accept the statement that two-thirds of all surgical tuberculosis is due to bovine infection, it behoves us to see to it that our milk supply is beyond suspicion.

Lungs.

(a) *Tuberculosis*.—When we come to consider diseases of the lungs as a cause of crippling, we find that pulmonary tuberculosis is conspicuous by its absence. Routine medical inspection revealed no evidence of definite pulmonary tuberculosis and only seven suspected cases out of a total of 15,605 children examined. Even among the crippled children at this age pulmonary tuberculosis was not definitely found though it was suspected in 0.6 per cent.

(b) *Bronchitis*.—Chronic bronchitis is responsible for 6 per cent. of the whole crippling. These cases of chronic bronchitis range in severity from cases of winter cough accompanied by snoring and wheezing rhonchi to the most advanced cases of bronchiectasis and bronchiectasis with large cavity formation, fibrosis and contraction of the lung. It is these latter cases which are responsible for most of the lung crippling; they are almost invariably the result of bronchopneumonia following measles, whooping-cough, and influenza, and are very apt to be diagnosed phthisis pulmonalis, especially when seen soon after the bronchopneumonia, when emaciation is marked. After long observation of many of these cases I have come to the conclusion that they are not tuberculous, the spit is invariably negative, and in spite of the most extensive cavity formation the general health improves under favourable conditions, and it is no unusual thing to find a child after prolonged treatment, apparently in robust health, with a chronic basal catarrh of both lungs associated with fibrotic change. Many of these cases I have submitted to my friends the tuberculosis officers for further observation and inquiry, and their conclusions have agreed with mine—namely, that the cases are non-tuberculous.

In my experience, then, phthisis pulmonalis is rarely found in children at 5 years of age, and I attribute the high incidence of this disease reported from some districts to the inclusion of these cases of chronic bronchitis and fibrosis.

Nervous Diseases.

As I have already mentioned, nervous diseases are responsible for 7.4 per cent. of the crippling found at this age. Unfortunately there is very little that can be done for these cases except in so far as we can prevent the formation of contractures in hemiplegias and spastic paraplegias, and by supplying suitable apparatus in the case of infantile paralysis enable the child to make the most of what power he has.

Mental Deficiency.

Mental deficiency comes next in the order of frequency, with a total percentage of 6.3. The cases which are diagnosed at this age are, of course, gross cases of low grade imbecility which are obviously for institution treatment and care. Unfortunately these do not nearly account for all the mental deficiency present among 5-year-olds. The higher grade cases which exist cannot be diagnosed till the child has been some time under observation in the infant department. In Glasgow we do not care to label the higher grade cases mentally defective till they have been given a two years' trial among normal children.

Anaemia and Malnutrition.

The cases of anaemia and malnutrition, which account for 3.9 per cent. of the total crippling, are those which show no symptoms of other disease, the debilitated conditions usually following on pneumonia or one of the infective fevers. In some of the cases a tuberculous family history can be elicited.

Miscellaneous.

The remaining 9 per cent. of crippling, due to eye conditions, mostly strumous ophthalmia, a few cases of heart disease—the acquired of those due to scarlet fever and rheumatism—and other miscellaneous conditions such as congenital and acquired deformities, need not be discussed in detail.

From the facts that I have laid before you you will see that by far the largest amount of crippling is due to entirely preventable causes. As we know rickets, surgical tuberculosis, anaemia and debility, and strumous ophthalmia to be curable under ideal hygienic conditions, I am convinced that it is by the same means that these diseases could be prevented, and that those

cases of chronic bronchitis which develop so frequently in debilitated children after bronchopneumonia would be reduced to a minimum. What we want, therefore, is first of all the provision of open spaces to allow of the free access of sunlight to a tubercle-free milk supply, better feeding conditions, the provision of good houses with every convenience for cleanliness and the total abolition of the slum.

DISCUSSION.

Dr. MILLER (C.M.O. Radnor) commented on the comparatively small number of children with suspected phthisis and inquired whether these were kept under observation. He also asked if Dr. Bruce could furnish any information as to the prevalence of rickets amongst breast-fed infants.

Dr. MORRIS (M.O.H. Neath) expressed the opinion that lack of exercise had much to do with the causation of rickets. He strongly condemned the carrying of the baby in a shawl wrapped tight against the mother, a custom which he noticed was as prevalent in Glasgow as in South Wales. The "shawl" babies always had rickets; the pram was infinitely better.

Dr. BRUCE, in reply, stated that all cases of suspected phthisis or malnutrition were kept under observation at the clinics before being passed on to the Tuberculosis Department. Some had been under observation for nine years without showing definite signs of tuberculosis. He could always tell by a child's legs whether it was a "shawl" baby or a "pram" baby, but the ricket-producing class seldom if ever possessed a perambulator. He frequently found rickets amongst the breast-fed babies, but could not at the moment give exact figures.

MATERNITY AND CHILD WELFARE IN SCOTLAND.

BY

MARY J. MENZIES, M.B., CH.B. (Edin.), D.P.H.,
Medical Officer, Scottish Board of Health.

THE object of this paper is to furnish a short record of the steps taken by local authorities in Scotland to create maternity and child welfare services under powers conferred upon them by the Notification of Births (Adoption) Act, 1907, the Notification of Births (Extension) Act, 1915, and the Maternity and Child Welfare Act, 1918.

In the application of the 1915 Act to Scotland very wide powers were conferred on the local authorities concerned, in that they were empowered "to make such arrangements as they think fit and as may be sanctioned by the Local Government Board for Scotland for attending to the health of expectant mothers and nursing mothers and children under five years of age within the meaning of Section 7 of the Education (Scotland) Act, 1903."

By a circular letter issued in 1915 the Local Government Board for Scotland invited local authorities to "submit schemes of arrangements in terms of the Act."

For the purpose of inspiring and assisting local authorities a comprehensive memorandum expounding the purpose of the 1915 Act was issued in 1916. To this were appended the regulations governing the payment of the 50 per cent. grant allowed by the Treasury. These regulations, apart from the clauses securing the administrative control of the Board retained in the regulations of later date, are rendered interesting when regarded in the light of the developments of after years by the nature of arrangements therein specifically excluded from grant. These were (1) residential treatment in hospitals, (2) operative treatment in hospitals, and (3) expenditure on food and milk.

For the further assistance of local authorities, a circular letter was issued in October, 1916, defining more clearly the nature of the arrangements that might suitably be included in schemes. On the terms of this circular, and on those of the circular letters of 1917 and 1918 containing revised regulations under which grants would be payable, have been based the schemes submitted for approval by local authorities.

These schemes, which only include arrangements made for attending to the health of expectant mothers and nursing mothers and children under 5 years of age, follow therefore certain general lines that can best be indicated by summarizing the expenditures defined by the regulations as grant earning.

These are, in short, expenditures on (1) salaries of medical officers, health visitors, nurses, and midwives engaged in maternity and child welfare work; (2) the provision for necessitous women of a midwife, or of a doctor for illness connected with pregnancy or aid during the period of confinement; (3) centres providing medical supervision and treatment; (4) institutions for the day care of children; (5) the temporary boarding out of children; (6) accommodation in maternity hospitals and provision for securing proper conditions for the confinement of necessitous women; (7) hospital accommodation for children; (8) accommodation in convalescent homes; (9) the provision of homes and other arrangements for attending to the health of children under 5 years of age whose parents cannot provide a satisfactory home for them; (10) experimental work; (11) educational work; (12) food to the necessitous; and (13) contributions made by the local authority to voluntary institutions.

Before expenditure on arrangements can rank for grant it must conform to certain conditions and be specifically approved by the central authority, now the Scottish Board of Health. Since 1918 there have been extensions of the regulations to admit the provision of nursing care and massage for children and the cost of accommodation and treatment in hospitals for cases of measles and whooping-cough.

During a period of acute distress occasioned in certain areas by unemployment in the coal-mining industry and the resulting trade depression, it became necessary for the central authority to define from time to time the conditions under which relief in the form of rations, food and milk, might be given to mothers and children. The special increase in expenditure due to the industrial crisis cannot be regarded as appropriate to a maternity and child welfare service carried on under normal conditions.

The absorption in the disbursement of relief of the attention of local authorities and of the members of their staffs normally employed in maternity and child welfare services, combined with the concurrent clamour for economy, has prevented the development of new services, but has not seriously interfered with the expansion projected in previous years and in course of being put into operation.

The population of Scotland (census 1921) is 4,882,288. The number of births in 1920 was 136,546, and the deaths under 1 year of age were 12,565. The infantile mortality rate in burghs varies from 0 to 208, and in county districts from 30 to 102. For 1921 the rate for Edinburgh was 98, for Glasgow 106, Aberdeen 108, and Dundee 114; for Scotland it was 90—the lowest rate recorded so far for the country as a whole.

Almost 3,000,000, or about three-fifths of the population, are maintained by the industries dependent on coal and iron centred in the Forth and Clyde valleys. They live for the most part in overcrowded conditions calculated to produce a high infantile mortality rate. It is therefore mainly in this area and in the cities of Dundee and Aberdeen that local authorities, supported by the pressure of public opinion, have since 1916 drafted schemes that are still in the course of development and go far towards providing an adequate service for the care of mothers and children.

The local authorities within the meaning of the Notification of Birth Acts, 1907 and 1915, are the 201 town councils, 8 county councils, and 99 district committees. Owing to the power to combine allowed by the 1915 Act as applied to Scotland, schemes fall into four groups, but there are differences in the nature of the schemes and in the extent to which particular services included have been developed, resultant on the diversity in the industrial character of the areas concerned.

Types of Schemes.

The following are the four types of schemes:

1. The one-burgh scheme, in which the administrative control is retained by the local authority. There are 84 burghs, 16 with a population over 30,000, with such schemes. The schemes of the smaller burghs within this group cannot be regarded as self-contained, since institutional accommodation has to be obtained without their areas.

2. The one-district scheme, in which local administrative control is retained by the district committee. There are six such schemes, situated in Dumbarton, Renfrew, and Lanark Counties. For the most part they are not self-contained, since institutional accommodation has to be obtained in other areas.

The most important of these one-district schemes is that of the Middle Ward of Lanark, with a 1921 census population of 218,789, and a birth rate in 1920 of 34.4. Its local authority, well known for initiative and progress, has since 1916 been gradually putting into operation an extensive scheme which, if expansion continues, should in course of time become self-contained. For the purpose of providing a maternity and child welfare service in this district, two medical officers and eighteen health visitors, including a superintendent of health visitors, are employed whole-time. Eight maternity and child welfare centres held in premises afforded by public halls that can be rented for the purpose are in operation. These centres are open once a week with a doctor in attendance for consultations, assisted by health visitors, and by voluntary workers who provide a supplementary social service. Close supervision is exercised over the midwifery service. A maternity hospital and training school for midwives has been established at Bellshill, with an annexe in the form of a hospital for infants at Blantyre. A rest and convalescent home for mothers and babies at Calderbank House completes the present arrangements.

3. The district combination scheme, in which burghs have combined with the county district in which they are situated. There are seven such schemes. In the Upper Ward of Lanark and in the districts of the County of Fife, administrative control is retained by the district committee. In Haddington County administrative control is delegated to committees on which the authorities concerned are represented. Twenty small burghs have thus secured economical services.

4. The county combination scheme. There are eleven such schemes sanctioned—namely, for the Counties of Aberdeen, Ayr, Berwick, Clackmannan, Dumfries, Kincardine, Kirkcubright, Midlothian, Moray, Perth, and Stirling. Whilst the Aberdeen County scheme is administered locally by the county council, the other county schemes are administered by joint committees representing the authorities concerned.

All of the county districts and the majority of the burghs within these counties have entered the respective combinations, forty-one districts and fifty-six burghs being thus provided with services. In Clackmannan and Kincardine Counties all the burghs are within the combination, whilst in Moray, Dumfries, Berwick, and Kirkcubright counties, Elgin, Dumfries, Duns, and Maxwelltown burghs respectively remain outside. Most burghs with a population under 5,000, realizing their inability unaided to furnish an adequate service, have sought economy and efficiency by combination with larger authorities. There still remain, situated for the most part in the northern and western sparsely populated areas where the infantile mortality rates are low even when judged by the present improved standard, forty-one burghs without child welfare services and seventeen counties in which no provision is made for the landward areas.

In order to bring into relief the results of the energy, initiative, and enterprise shown by the public health authorities during the succeeding years it is necessary to refer to the official provision existing in 1915.

Medical Officers and Health Visitors.

There were at that time, officially employed on duties dependent on the adoption of the Notification of Births Act, 1907, two women doctors and twenty-nine women visitors whole-time, and nineteen women visitors part-time. Now, in 1922, in addition to the medical officers responsible for the administration of the 108 sanctioned schemes, there are eleven medical officers employed whole-time on child Greenoc.

Ward of Lanark. There are at least sixteen whole-time medical officers of local authorities and twenty-six part-time medical officers of health taking an active practical part in maternity and child welfare work by serving as medical officers of clinics.

A large number of general practitioners are drawn within the services as medical officers of centres, whilst specialists are attached to hospitals established by local authorities and to other institutions included in schemes. Engaged officially in home visiting are 172 whole-time, 201 part-time, and approximately 800 voluntary health visitors. Inspection of midwives, which has resulted in a marked improvement in the standard in some areas, is performed by medical officers of health and by health visitors appointed to assist.

Maternity and Child Welfare Centres.

In June, 1916, there were 14 maternity and child welfare centres in Glasgow under municipal control; and, provided by voluntary effort, there were 5 in Edinburgh, 5 in Aberdeen, 1 in Dundee, and one in Motherwell, those in Aberdeen being in close touch with the public health department. There are now 166 centres almost entirely maintained by the public health authorities.

Institutions for the Day Care of Children under 5 Years of Age.

There has been no marked increase in the number of institutions of this type, but by the reconstruction of old buildings and the provision of new buildings for existing institutions, transferred from the voluntary associations by which they were established to the public health authority, the standard has been much improved. For example, a model day nursery, intended to replace one existing in unsuitable premises, has by its presence, converted, in the Cowcaddens, Glasgow, an ugly piece of waste ground, formerly a noisome slum, into a picture that delights the whole neighbourhood and charms every passer-by.

An old-fashioned square-built house with a large garden presented to Stirling Burgh and converted into a centre, day nursery, and, by the aid of the Carnegie United Kingdom Trust, a garden play centre, is another example of a beauty spot in a rude neighbourhood.

It must be deeply regretted by all workers familiar with the conditions of life for young children in slum areas, where children under 5 are kept in bed undressed, and without toys, games, or other amusements, until mid-day, whilst the mother does her housework—the only available playground being the common stair or the gutter—that more effort has not been made by public health or education authorities to bring, by the establishment of nursery schools, within the reach of these little ones the ordinary training afforded by games and toys to the child of the middle class.

There is a model nursery school at the Phoenix Park, Glasgow, established by voluntary effort and now maintained by the public health authority. There are three in Edinburgh, established and for the most part maintained by voluntary effort. 'Toddlers' play centres serving a somewhat similar purpose exist to the number of six in Edinburgh, one in Stirling, and one in Elgin, established by voluntary effort, but, with the exception of that in Elgin, assisted by grants from the local authorities.

Institutional Accommodation for Maternity Cases.

Of the six maternity institutions existing in 1916, five have now some form of agreement with one or more local authorities and are thereby included in schemes. In conjunction with the local authority, an ante-natal annexe to the Aberdeen Maternity Hospital has been established. In agreement with the Edinburgh public health authority, the Royal Simpson Memorial Hospital has provided ante-natal beds and an ante-natal out-patient department of great benefit to the community. This hospital has also agreements with other local authorities in regard to the admission of cases from areas outside the burgh.

Agreements have been made by the Glasgow Maternity Hospital with the Glasgow Town Council and with other authorities for the admission of cases.

The increasing demand made for institutional accommodation for maternity cases has led to the provision of new institutions by local authorities. The district committee of the Middle Ward of Lanark has converted Bellshill Hospital into a maternity hospital of forty beds. The Town Council of Paisley has provided a maternity hospital of eighteen beds in Barshaw House, its own property situated in the public park. The Joint Maternity and Child Welfare Committee of the Ayr County Combination has twelve maternity beds in Seafield House Hospital, a mansion house purchased and equipped by the authority. Greenock Town Council converted a house gifted for the purpose into a hospital of six beds.

Maternity homes for normal cases, providing in all about forty-eight beds, have been established by Airdrie and Coatbridge, by Kirkealdy, Dunfermline, and Dumfries.

Hospital Accommodation for Children under 5 Years of Age.

The large voluntary hospitals for sick children have not made official agreements with local authorities and are not directly included in schemes. They, however, deal with cases referred

to them, that by their nature have a claim on in-patient or out-patient treatment. To meet a claimant want, special hospital provision for infants has been made by the local authorities of Aberdeenshire, Paisley, the Middle Ward of Lanark, and Ayr County, and has been secured in Dundee by arrangement with the infant hospital, and in Greenock by a small voluntary hospital partly maintained by and managed in close co-operation with the public health department.

The arrangements of local authorities generally are supplemented by a vast amount of voluntary effort of inestimable value, represented by organizations for the purpose of providing assistance in the clerical, social, and educative services of child welfare centres; by the provision of accommodation in hospitals, convalescent homes, and other institutions for mothers and children, utilized by local authorities for cases coming under their care for which they have not themselves made other provision; by nursing associations that furnish the part-time health visitors that are employed in rural areas; and by associations in Edinburgh and Glasgow that supply about 800 voluntary health visitors.

Various methods of procedure have been followed by local authorities putting into operation child welfare schemes, and that of Edinburgh may be regarded as one type. There the local authority, in accordance with the scheme drafted by the medical officer of health, proceeded to include and co-ordinate such voluntary associations and institutions within the burgh as were suitable and were willing to enter into an agreement. These included voluntary health visitors, infant health centres, consultations for women and children, dispensaries, day nurseries, nursing schools, play centres, hospitals, and homes for mothers and infants.

A policy of non-interference with the private management of institutions providing special services under terms of agreement, followed by the town council, encouraged institutions that were at first reluctant to do so to come into the scheme. In order to cope with the increasing work of the service, a whole-time medical officer was appointed and the clerical and whole-time health visiting staff increased. With a view to improving the standard of the service, premises were reconstructed, institutions were transferred to other premises, and additional centres opened. A beautiful home was provided for delicate children at Gogarburn. On the fusion of Edinburgh and Leith, the institutions provided by the latter town council automatically came within the scheme.

No report on maternity and child welfare services in Scotland would be complete without a reference to Motherwell, where since 1912 home visiting has been undertaken by a part-time service organized by the Motherwell Nursing and Ambulance Association on behalf of the local authority. As home visiting developed, an extension of the nursing service was needed to meet the requirements of the statutory work; and whereas in 1912 there were three nurses employed in district nursing, there are now thirteen nurses including a superintendent engaged in the co-ordinated service for voluntary and statutory home nursing and visiting. The new combined burgh of Motherwell and Wishaw, Clydebank, and Falkirk are the three larger burghs in which this arrangement obtains, the women employed in these home-visiting services being Queen Victoria Jubilee Nurses.

To Motherwell was offered the model maternity and child welfare centre bestowed on the Scottish people by the Carnegie United Kingdom Trust. This important institution includes a maternity and child welfare centre, a very complete treatment centre, a cleansing centre, and provision for a mothers' club and other suitable educative activities.

The scheme put into operation by the combining authorities of Ayr County presents certain points of interest, since it arranges for a maternity and child welfare service almost entirely staffed by part-time officers. The four district committees and the town councils of all the burghs within the county, except Ayr, Irvine, and Kilmarnock, agreed to combine and to exercise their powers through a joint committee containing representatives of the combining authorities, and fifteen co-opted members, of whom five must be women. The population of the area, including that of the burghs served by the arrangements made by the joint committee, is according to the census taken in 1921, 215,931, and the births were 5,722 for the year 1920.

In order to secure an adequate health visiting service, a County Nursing Association had to be brought into being, stations for district nurses fixed, and areas to be served determined until

the whole population of the county was grouped into areas for the purpose of being supplied with a nursing service. Nursing associations had to be constituted in the areas not provided with such. For the purpose of aiding in the creation of additional associations and the co-ordination and supervision of the statutory work of all the nurses, a superintendent of health visitors was appointed. There are now thirty-five stations for district nurses, and forty-one nurses are employed part-time in health visiting. Four whole-time health visitors are, however, also required for wide areas in which district nurses are not available. In burghs and mining villages twenty-six maternity and child welfare centres have been opened at which consultations by doctors in general practice are held, for the purpose of the prevention of defect and disease in mothers and children.

The combined local authorities have shown initiative and resource by establishing a maternity and a sick children's hospital at Seafield House, Ayr, where in an institution, equipped as a hospital, situated in delightful surroundings that will allow of future expansion, twelve maternity beds and accommodation for thirty-four children is provided.

A most interesting scheme is that of the Western District of the local authorities of the four burghs—

Prestonpans, and Tranent—have combined with the district committee. The scheme is administered by a joint committee representative of the local authorities. Under this scheme the home visiting is carried out by three whole-time health visitors employed by the county council, who give part time to health visiting, part time to tuberculosis, and part time to school nursing. They therefore have the care of the children from birth to 16 years of age, and not only are valuable agents in the prevention of disease, but also have a most beneficial influence in the homes throughout the area. The value of the child welfare centres, three in burghs and three in mining villages, held in public halls with inexpensive equipment, with a doctor and health visitor in attendance, is undoubtedly greatly appreciated by the mothers of the community.

Hospital treatment is obtained by sending maternity cases to the Royal Maternity Hospital and by referring sick children to the Royal Hospital for Sick Children in Edinburgh.

DISCUSSION.

Dr. McKAIL (Lecturer on Public Health, St. Mungo's College, Glasgow) applied a note of interrogation as to whether all this public health work tended. Was it towards the Spartan system of taking the children from the parents and doing everything for them? We should not drift into this without definitely visualizing the result.

Dr. H. BRACEY (Assistant Schools Medical Officer, Warwickshire) asked if Dr. Menzies had correlated the infantile mortality rates of different areas with the infant welfare schemes on the one hand and the general sanitation of the areas on the other, in order to discover the relative importance of the former and the latter in reducing infantile mortality.

Lieut.-Colonel FREMANTLE, M.P., hoped that Dr. Mary Menzies would not occupy too much of her time in mathematical inquiries, as suggested by Dr. Bracey, as these, as a rule, only proved what was already known. It was the existence of these appalling conditions which called forth the best welfare effort. Of the remarkable schemes recorded in the paper under discussion the most satisfactory feature was the use made of all the various agencies—national, municipal, voluntary, part-time and full-time. It was co-operation of this kind that led to efficiency. We must also remember that the greater the responsibility thrown on the parents the more likely was parenthood to be discouraged, the birth rate depressed, and the recruiting of the nation arrested.

Dr. MARY J. MENZIES, in reply, said that Dr. Fremantle had already given more than a sufficient answer to Dr. McKail and Dr. Bracey. Less than 1/10 per cent. of the population were engaged in looking after the others. The recent fall in the infant mortality rate for England had more than improved sanitation behind it. The sanitary improvements which had been going on for the previous thirty years had not been accompanied by a similar reduction in infant deaths. The infant death rate should be considered along with the defect rate amongst children admitted to school, and a fall in the former should be associated with a fall in the latter.

DISCUSSION ON INDUSTRIAL FATIGUE AND VOCATIONAL SELECTION ON A BASIS OF PHYSICAL INQUIRY.

OPENING PAPER

BY

DAVID MCKAIL, M.D. GLAS., D.P.H. CAMBR.,
Certifying Factory Surgeon, Glasgow Eastern District.

THE study of industrial fatigue is the study of a very complicated problem, and one beset by many difficulties.

In the first place, what do we mean by the term "industrial fatigue"? The words themselves connote, taking them reversely: "fatigue"—weariness, tiredness, or exhaustion from bodily labour or mental exertion; and "industry"—habitual diligence in any employment, either bodily or mental; steady attention, careful application, activity, assiduity. Taken together, they denote the worn-outness due to physical toil or bodily exertion or mental effort, either from its intensity or violence or from its continuance or protractedness. Such fatigue was undoubtedly common when the hours of labour were prolonged to twelve, fourteen, or even sixteen a day, and when heavy loads and exhausting tasks were almost entirely moved or accomplished by the use of human power. Even to-day there are numerous examples of arduous toil, while, on the other hand, the hours of labour are, for the most part, markedly shortened. This kind of fatigue is such that it tends to produce physical deterioration in those engaged in it, so that the wastage is excessive, and, if not absorbed by lighter industries in the neighbourhood, leads to heavy calls on the communal provision for the disabled. It therefore borders on the pathological, because it taxes the recuperative powers from day to day and from week to week. The worker is thus always partially intoxicated with the products of exertion, excretion lagging behind production. In this state he is more liable to the commoner infections and in a less fortunate position to bear up against them. His resistance to infection is depressed and his response to attack is enfeebled. While other consenting causes are at work in effecting these results—namely, the unhygienic conditions often associated with indoor manufactures—the toxæmia is probably the most important individual cause. The provision of more fresh air inside the factory might only result in increased production of effort and so of toxin, whereas the tiredness resulting from the toxæmia makes the worker unwilling to exert himself further in his leisure to take "exercise" in the open air.

But it is undoubtedly true to say that the present generation is emancipated from much irksome labour that the preceding ones could not avoid, however much they might wish to do so. And in the last few years the reduction of the hours of labour to eight in many employments has, with the increasing use of motive power, practically eliminated this exhausting form of fatigue in these, and reduced the opportunities of its study very considerably. With the improved conditions, the problem has developed along physiological lines. The ill effects of the fatigue of exhaustion were often marked and obvious: those of the minor form are mostly subjective and personal to the worker and therefore not easily recognizable to the observer. It has thus been necessary to redefine the meaning of the term "industrial fatigue," and the definition now in general use is that of the Health of Munition Workers Committee, to wit, "the sum of the results of activity which show themselves in a diminished capacity for work"; or, to paraphrase this somewhat sibylline utterance, "activity, mostly muscular in character, but with the attendant and necessarily associated nervous action, when persisted in, as in the performance of a definite task or amount of work, produces consequent changes in the bodily structures involved, which in their accumulated effects reduce the rate of output of work." In some forms of activity this diminution of power or capacity is readily observable and can be used as a measure of the "industrial fatigue" produced.

It is needful to remind ourselves that "fatigue" in some degree follows every action of the human organism. When the rate of its production does not exceed the rate of its removal by the appropriate mechanism, then activity might be indefinitely prolonged. As a matter of fact, however, there is

always a lag in its removal, rest of the affected parts being an absolute requirement for full repair. If the fatigue is in reasonable measure, the nightly rest is sufficient to bring back the vivacity, and the person starts refreshed to his labours. Any daily lag can usually be overtaken by the weekly rest-day, which has no doubt been evolved from long observation by mankind as a necessity for man and beast when working to a daily programme. Otherwise, there are large bursts of output of energy, followed by pauses or rests.

The limitation of industrial fatigue to this minor form has this result, that a considerable body of research of past years is already available for application if the various interested parties are willing to utilize it. "All that is new is not true, and all that is true is not new" is an aphorism to be well remembered in these times. Numbers of men have applied themselves to the problems of the fatigue of exercise and work in the past two generations, and some have left valuable observations thereon. Unfortunately, much of the applied knowledge has perished with the persons themselves, belonging to that vast amount of discovery which is made in each generation but is not transmitted in permanent form.

Alongside of all this is the work of the physiologists, such as Waller, the inventor of the dynamograph, Mosso of the ergograph, and many studies in fatigue which have been widely applied in the field of education. In a series of researches in the industrial field Professor A. F. Stanley Kent has brought all this knowledge to bear in a masterly way on actual working conditions. Numerous succeeding observations have served to confirm and extend these, and there exists at present a well-attested body of knowledge concerning what are the best industrial conditions for many employments: the next step is to put them into practice. But that, unhappily, is not yet, for the present confused economic conditions have dealt a death-blow to many welfare schemes and the day of deliverance is deferred. The field of usefulness will thus be limited to ameliorating the extremely defective conditions where they exist, and in assisting in those trades and industries where the economic pressure is not so prohibitive. Not uncommonly, the occupations in which interference is most needed are those in which least is allowed, whilst in many luxury trades, with admirable conditions, the provision of extra comforts and facilities is spontaneous and considerable.

The work begun under the Industrial Fatigue Research Board in 1918 opened a promising field in which much useful spadework has already been accomplished. This is still largely in the observational stage, and a considerable time must elapse before accurate deductions can be arrived at. It will be useful to quote the terms of reference to this Board, as a basis for further remarks:

"To consider and investigate the relations of the hours of labour and of other conditions of employment, including methods of work, to the production of fatigue, having regard both to industrial efficiency and to the preservation of health among the workers."

When we proceed to attack these problems, certain difficulties at once arise. In some industries the pace of work is made by the individual, in others by the machine; in some the work is arduous, in others light; in some the output is easily measured, in others this is difficult; and so on. Other factors emerge which disturb the solution—namely, the differences in original endowment of strength and vitality among the workers; the varying reactions to their work and environment; the home conditions, especially whether work is demanded there after the day's toil; and the social habits in regard to rest, sleep, exercise, food, and amusements, all of which cast an influence on the amount of work done, the attention bestowed on it, the liability to accident, and the incidence of sickness. The many possible combinations and variations among all these parts of the individual's life-cycle make comparisons from worker to worker a matter of difficulty, and enforce the need for caution in drawing conclusions. As the reporter wisely says on page 6 of the Second Annual Report:

"The difficulties of industrial research of this kind are formidable, and can only be fully realized by such as have had actual experience of it. Almost the whole of the investigations deal with a number of variables, none of which can be wholly controlled, and consistent results can only be secured by taking immediate advantage of opportunities as they offer, which under the industrial conditions of

the last few years may suddenly lapse before investigation is complete."

Let us, then, "consider and investigate the relations of—

- (a) The hours of labour,
- (b) Other conditions of employment,
- (c) Methods of work,

to the production of fatigue, having regard both to industrial efficiency and to the preservation of health among the workers."

A. The Hours of Labour.

The claim by the coal miners for an eight-hour day, made statutory in 1908, familiarized the nation with this part of the problem—namely, the consideration of the hours which should be worked at arduous employments. The seed thus sown was suddenly ripened into fruit in the post-war period, when, early in 1919, the adoption of an eight-hour day became an accomplished fact in most of the industries in this country. Incidentally, the shortening of hours worked raises the important questions of the arrangement of spells of work, rest pauses, and pace of work, as well as output and wages inquiries. The whole subject is thus intimately bound together, and interference with a part involves the whole. Accepting the eight-hour day, and leaving aside any economic considerations, what is the best division of the hours of the day between work and food and rest and sleep? To bring the matter to a point, I venture to put forward the following alternative arrangements, based on a wide variety of reasons, as the most suitable. I prefer the first, as conforming more to established meal hours in the general life of the community. Other reasons are indicated in the argument.

Rise, wash and dress; light

breakfast	6 a.m.	7 a.m.
Morning spell of work ..	7 to 9 a.m.	8 to 10 a.m.
Breakfast and rest pause ..	9 to 10 a.m.	10 to 11 a.m.
Forenoon spell of work ..	10 a.m. to 1 p.m.	11 a.m. to 2 p.m.
Dinner and rest pause ..	1 to 2 p.m.	2 to 3 p.m.
Afternoon spell of work ..	2 to 5 p.m.	3 to 6 p.m.
Tea and rest pause ..	5 to 6 p.m.	6 to 7 p.m.
Rest and recreation ..	6 to 10 p.m.	7 to 11 p.m.
Sleep	10 p.m. to 6 a.m.	11 p.m. to 7 a.m.

The maximum working spell shown above is three hours. For work requiring steady application and attention, I would reduce this to two and a half hours. Where the work is intermittent, it may be lengthened to three and a half hours, but certainly not to four hours. Even where the duties are so mild as to make four-hour spells possible, there are other reasons why we should prefer the shorter period. Want of variation and confinement induce languor and dullness, and continuance of work thereafter can only be done by the exercise of superior or excessive mental stimuli, and the resulting fatigue is more slowly recovered from. This is more observable in work accomplished in fixed—that is, in sitting or standing—positions, and occasioning local fatigue of hand and eye. In arduous work, a four-hour spell should not be allowed where the labour is continuous. In any case, the work should be arranged with frequent pauses to allow of rallying. Certain occurrences in such employments suggest that men are at times overcome with faintness following excessive exertions. There is no doubt that the heart is dilated under bodily strain, but when the latter is not too great or too prolonged, or too often repeated in a given time, it quickly recovers its elasticity. With increase of years, this power of recovery deteriorates and this should be definitely recognized in all such workers.

But the final appeal as to the length of such spells is the testimony of the individuals subjected to them. At present, unfortunately, it is difficult to get such testimony from the persons concerned, because they for the most part are unused to describing their sensations or of analysing or estimating their relative importance. The investigator, likewise, is, as a rule, at the considerable disadvantage of having no practical acquaintance with the employment, and is thus unfamiliar with its special difficulties. It is interesting in this connexion to note that Miss May Smith, the investigator allotted to the laundry industry by the Industrial Fatigue Research Board, took an early opportunity of "gaining first-hand experience by working personally in a laundry for a few weeks" (First Annual Report, p. 18). Speaking from personal experience, I can testify that when engaged, as a lad of 15, for several weeks in a holiday period, at the somewhat strenuous task of pressing Glasgow bricks (about 10 lb. weight), I managed the

6 a.m. to 9 a.m. and the 3 p.m. to 6 p.m. spells all right, but the 10 a.m. to 2 p.m. spell I found too long, and from 1 p.m. on felt wishful to stop. The work was done by the piece, by a gang of three, one of whom worked the hand-press and the other two placed the bricks and carried. The pace was steady, with changing of tasks and occasional pauses when called for. I still vividly remember the sinking feeling which came on after 1 p.m. daily. But, it will be objected, and rightly too, that the experience was short-lived, and in the language of the Second Annual Report of the Industrial Fatigue Research Board, p. 7:

"Any considerable change attendant on labour conditions is followed by a period of readjustment which continues for a long time before constancy and equilibrium become re-established. It is therefore only with quite special caution and circumspection that inferences can be drawn from results obtained during such a period, although they may very probably be of special value for collation with normal results obtained later on."

A later experience of six months' duration in recruiting and national service boards has convinced me that when there is steady pressure of work with little or no intermission, spells of two and a half to three hours should be a maximum. In this as in some forms of industry there is a steady alertness of attention, combined with a moderate output of muscular energy. The "other conditions of employment" were probably often similar to that of a dusty employment, and no doubt conducive to the fatigue of attention that supervened in the third hour.

With regard to the morning period of 7 a.m. to 9 a.m. I adduce the following points. Collis and Greenwood (*The Health of the Industrial Worker*, p. 25) quote Dr. Edward Smith as writing in 1861:

"In our opinion no laborious occupation should be followed in this climate before 7 a.m., and it ought in all instances to be preceded by the breakfast. . . . The period of the day in which the human system is the most vigorous and fitted for labour in our climate is from about 8 or 9 a.m. until about 4 or 5 p.m., but it is sufficiently vigorous for a longer period."

Again:

"Rest is a necessary alternative to labour, and as small meals are conducive to muscular exertion, it is worthy of consideration if those who are engaged in manual labour for many hours would not perform it with more ease if there were more frequent but shorter intervals for rest and for meals, instead of the three meals a day at long intervals with the single long interval of rest between 8 p.m. and 6 a.m. It is very probable that more work would be done, and at less cost to the workman."

Now of these two statements, the first seems against the scheme suggested, and the second in its favour. But the opposition is only apparent. The important points are to have more frequent intervals for rest and meals, and to have breakfast before starting work. To take the last point first, it is a thing not easily to be attained by nine-tenths of the labouring classes under present conditions. And why? Because, so long as work begins before 9 or 10 a.m. there will be two factors to contend with—want of appetite for a reasonable sized meal, and the household preparation of the same. Whether it is late hours or late feeding, or unhygienic sleeping conditions, or fatigue or exhaustion, or insufficient or improper diet, or climatic conditions, or late rising, or any combination of these, there is a widely prevalent inability to take breakfast immediately on rising, and more especially among women. Even in children mothers commonly state that the child takes little or nothing before going to school. For children and adults the advice is similar: if starting work at 8 a.m., and no travel time required beyond a few minutes, get up at 7 a.m. at latest, and if possible have your meal cooked for you and set for 7.30 a.m. But this introduces the problem of the mother, who in general is the home comfort provider, and would have to rise at 6.30 a.m. Then there are the unmarried men and women, and widows, many of whom have to provide for themselves. On the other hand, with the suggested programme, the person can take a light repast before going out to start work at 7 a.m., and come back for a prepared breakfast at 9 a.m., or have it at the works' canteen.

But this advice runs counter to many presently established customs, chief of which is the lateness of city hours. That is why I prefer the 5 p.m. stoppage of work in the scheme, in the hope that the various recreative outlets for the young person

and adult may have the chance of an earlier start, and so reliefs their devotees to get to bed by 10 p.m. as in former days. This would be the true daylight saving, and not the spurious article, which is detrimental to the young and old in the cities.

Before leaving this point I give two real experiences. The first is personal. When in the R.A.M.C. (for a period, January to April, 1916) I was in medical charge of a Reserve Infantry Brigade. The plan of duties was: Sick parade, 7 a.m. to 9 a.m.; inspection and vaccination of arrivals, 10 a.m. to 1 p.m.; inspection of drafts, inoculation for typhoid, etc., 2 p.m. to 4.30 p.m. I only claim that the duties were constant from the start; later they became more so. I got up at 6.15 a.m., dressed, and walked almost a mile to the medical hut. There was an offer (which I refused on account of its unpalatableness of a morning cup of tea. I breakfasted at 9 a.m., lunched at 1 p.m., had afternoon tea at 4.30 p.m., and dinner at 7.30 p.m. Now the point I wish to make is that, contrary to my expectation, I felt quite well for practically the whole of the time, at all the sessions, the early one included. I still believe that a pleasant morning drink would probably have been of value. Over the whole period I only missed one morning, and then it was due to a cold. It is true that the experiment was limited in duration, but it was also abrupt in its onset from a 9 o'clock start, preceded by breakfast.

The second experience is one which was elicited in the course of a visitation for other purposes. The patient was attended by the sharer of her single apartment, a Mrs. M. McB., aged 69 years. Something the latter said attracted my attention, and I soon found myself in the act of cross-examining her on the life of a weaver. I specially avoided leading questions and cautioned her against answering unless she had a definite opinion on the subject. I found that she readily understood my position, and the following summary represents her own views on the various points dealt with.

Mrs. M. McB. started work at 14 in a warehouse, but was advised by a doctor to change to weaving on account of her "chest." About 15 years of age she started as a learner in a weaving factory, making muslins and blue cloth. The hours of labour were: 6 a.m. to 9 a.m., 10 a.m. to 2 p.m., and 3 p.m. to 6 p.m. About eight years later she was married, and kept her home for the next sixteen years. She had five children. Her husband died at this time, and as the parish only allowed a shilling a head a week for the children who were not of working age, and nothing for herself, she went back to the "mill" two days after his burial. (He had been ill and off work for a long time previously.) She continued up till 1919, always at the same hours, except from 1917 to 1919 (two years), when the hours were: 8 a.m. to 12.30 p.m. and 1.30 to 6 p.m. During these two years she was weaving khaki cloth. Her wages latterly were 14s. weekly but after the bonus 23s. She preferred the hours starting at 8 a.m. for the later start. She was always a late bedder, sitting up to 12 midnight, and liked to read at night. With these longer spells she managed the first all right (except below re food) but in the afternoon about 4 p.m. she got tired and sleepy and for half an hour had a fight to keep alert (she would be about 65 years at this time), but this feeling would then pass and for the rest of the time she was "at herself" again. In spite of the later start she could not take a proper breakfast. Owing to the long spell from 8 a.m. to 12.30 p.m. she found she could not exist until the end of it without some food; but no break was allowed, so she bought about half a pint of milk in a can, and sipped it at intervals. Sometimes she had a biscuit. Her whole diet at this time was something like this:

Breakfast, 7.30 a.m.: Cup of tea and half slice of bread with or without egg.

Forenoon, 10 a.m.: Half pint of milk and biscuit.

Dinner, 12.30 p.m.: One slice of bread or a scone and tea, and cheese.

Tea, 6.30 p.m.: Porridge and milk, bread, and tea.

Asked if she had anything to say in favour of the old hours she volunteered the statement that after the morning spell (6 to 9 a.m.) her appetite for breakfast was better. She had no specially vivid recollections of the other spells, except that there was often a wish that it was stopping time. The early morning rush to work, however, she spoke of with great feeling: how she often left the house and her children about 5.30 a.m., with little or no food, hurrying along the streets for a mile and three-quarters to the weaving factory. Many times she arrived there in an exhausted state, and for the first half-hour of work was quivering and unbalanced and with imperfect vision. On other mornings, behind time, she saw the gate shut as she drew near; she was "quartered"—that is, had to wait outside the gate until 6.15 or 6.30 as the case might be—and had 1d. deducted from her wages; if later than 6.30 a.m., then the next time of entrance was after breakfast, or 10 a.m., with a deduction of 3d.

This unvarnished tale points its own moral. One would like to see this morning spell abolished altogether, and so have the manual worker placed on the same plane as the office or bureau worker. That would mean a six or seven hours day. There are no doubt some forms of industry in which it could be done "having regard to industrial efficiency." From the point of view of "the preservation of health among the workers," who that has seen the nation's manhood as it presented itself for recruitment from foundry and factory can doubt that those young-old men of 40 to 50 years owed their premature ageing largely to the stress of long-continued toil from the earliest years?

Further inquiries have but served to confirm the main points evoked in the above recital. There are still some who would prefer a return to the old long hours, from various reasons. But the majority prefer the later hour of starting (generally 8 a.m.), while admitting that they could not carry on but for a "piece" or cup of tea about 10 a.m. One worker liked the old hours worked (ten a day) as being less anxious then about her output. There had been no speeding-up of the machinery, so the inference seemed to be that she was missing the "rests" which she could afford on the longer spell.

Another objection to the 7 to 9 spell is that it increases the stoppages and starts, and working time is always lost then. Thus before breakfast and dinner, those who do not go home for meals begin to prepare their tea, etc. Those who go home, on the other hand, work on. It seems unnecessary to point out that if any favours are going, the workers who have to leave the factory and travel home and back again should get them, and that the stay-ins have all the time to prepare and take their food.

The main objection to the three-period day with two breaks will come from those who believe that after every start there is a "warming-up" time required, and that the repetition of this results in serious loss of working time. This is still a matter for further investigation. Different workers show different habits, but there is no doubt that, in the mass, the start is gradual at the first period. After that the observations are too variable to make a definite statement. In any case it seems to me that this is an individual characteristic which is likely to show itself in another form when we try to evade it. As long ago as 1884, Mosso, when studying ergographic tracings of muscular contraction, found that (*Fatigue*, Drummond's translation, 1915, p. 90 et seq.):

"The profile of the curve, that is the line which is obtained by uniting the summits of the contractions, forms a curve which varies in different people. I have been unable to find a reason for this fact, and have ended by convincing myself that it is in truth a constant feature which indicates the diversity which every one presents, in his way of becoming fatigued. . . . Some suddenly feel tired and give up work, while others, more persevering, gradually expend their energy until by degrees complete exhaustion supervenes."

Now, it may be objected that there is not much real fatigue, in Mosso's sense, in these times and in many forms of industry. Whether that is so or not, there can be no doubt that the repetition of muscular acts, however simple, unless followed at appropriate intervals by a period for recuperation, will produce that fatigue which shows itself "in a diminished capacity for work." In the heart muscle we have the great example of unceasing action, but on analysis this proves to be a perpetual alternation of a period of effort immediately succeeded by a pause period, twice as long in point of time. We must choose therefore one of two conclusions:

1. The worker must be permitted to work in an unsystematic manner, working and resting as the natural feelings dictate; or,

2. We must provide spells of work with definite rest pauses, and these must bear a relation to each other, which will vary with the other conditions of the work.

The first solution is the one adopted by the old-time home worker, and is a well-known one among intellectual workers, who are prone to overwork when the mood is on, and then have to lie fallow until reinvigorated. This method, however, did not fuse well with the introduction of power-driven machinery and factories, and has practically disappeared except in the smaller country districts, where the home worker can arrange his day's programme as his wishes dictate.

The second conclusion is therefore the only one left, and the object of this discussion is to elucidate the various parts of it.

B. Other Conditions of Employment.

The other conditions of employment are undoubtedly influential in the onset of fatigue, in industrial efficiency, and in the preservation of health among the workers. Many of them are not so subtle of solution as the problem we have just been studying, and their improvement is largely a matter of ways and means. Such are good buildings, furnishings, lighting, heating, and ventilation. For most factories, the application of the well-known principles of hygiene are sufficient. In a few, special difficulties arise: heat and moisture in cotton-spinning; excessive heating in glass-blowers and iron and steel workers; dusts and poisonous gases and liquids; and poor lighting in mines. Even here much can be done by willing co-operation on the part of master and man, although, unhappily, lack of this still exists. Professor Gilman Thompson, of Cornell University, New York, writing in 1914 (*The Occupational Diseases*, p. 77), divides employers of men in hazardous trades into three classes:

- (a) Those willing and sometimes eager to co-operate in the betterment of their working conditions.

- (b) Those who have already adopted all practical means of avoiding disease hazards for their workmen.

- (c) Those who assert, through indifference or ignorance, that such alleged evils as industrial diseases do not exist, at least in so far as their own establishments are concerned, or that, if they do, they are solely due to the workman's own negligence.

Our latest authoritative writers on *The Health of the Industrial Worker* (Collis and Greenwood), 1921 (p. 40), make the following remarkable statement:

"Looked at from another point of view, the student of the human machine and of its requirements to maintain health and efficiency is astonished, first, to note how the reasonable recommendations of important committees and Royal Commissions are passed by unheeded, while attention is paid to subjects pressed to the front by the uneducated voice of labour, or required in the interests of production. . . . Next, legislation is observed seldom, if ever, to lead reform, but to follow in the wake of progress, adopting the procedure of the more advanced employers of the time."

Let us leave it at that. Progress is slow. We still need a Carlyle to thunder out that "Supply and demand is not the one Law of Nature: Cash-payment is not the sole nexus of man with man" (*Past and Present: The Modern Worker*, chapter ix).

C. Methods of Work.

Under this heading is included such things as (1) the organization of the workshop or factory for the task in hand; (2) the adjustments of the worker and the machinery to each other; and (3) the different movements in each worker's task. All these are highly important in abolishing waste of energy on the larger as well as on the smaller scale. So much is this the case that in large factories with a standardized output the production can be enormously increased, thus allowing for reduction of hours with increase of pay. Although this highly desirable result cannot be generally obtained, valuable amelioration of working conditions have already been effected and more is in prospect. The training of the worker in the most approved manner of performing any set of motions which are in repeated use at the employment is now admitted to be of economic as well as of physiological value. But here as elsewhere caution must be exercised. The adjective "clumsy" is often used to stigmatize efforts which are markedly awkward or ungainly; the danger lies in using it for some set of motions which are unusual, and different from the "herd" method. The writer has been informed of a girl in a toy factory, who came from a mentally defective class, and whose mode of working attracted attention by its being different from the common one. On close study it was seen to be an improved method, and when all the girls were taught it the output was definitely increased.

Workers engaged in complicated co-ordinations and when speeding-up on piece-work sometimes adopt swaying or rhythmic movements of the trunk to accompany the movements of the hands and arms. This is seen notably in making chocolate biscuits, where the worker sitting at a table takes a biscuit with the left hand, places it under a shaped opening, through which

it receives a layer of chocolate cream, smeared over it from a spoon held in the right hand. She then removes the biscuit, inverts it over another biscuit which adheres to it, and places the completed article on a tray (all with the left hand), and immediately starts the process afresh. The whole action is not unlike the problem of touching the top of one's head at regular intervals with the right hand while the left goes through a series of performances unrelated to this act and requiring a greater expenditure of nervous energy. An imbalance is produced with increased excitability. Relief to one's feelings is got by dispersing the pent-up energy in other movements, which in this case is often a circumduction of the trunk on the hips, producing an effect not unlike that of the "helly-dance" of some savage tribes. This added movement is closely related to the lip and tongue movements seen in children learning to write, due to the excess of energy put into the task, some of which overflows into adjoining motor centres. To see such a girl at work suggests the possibility of untoward results from undue speeding-up, most likely to take the form of "neurasthenia," or being "run down" as the workers themselves would phrase it. The body motion itself, when excessive, might likewise originate other symptoms, allied to those attributed to the old treadle sewing machine. Perhaps some of our welfare workers may have had voluntary evidence on this point; it is not one on which suggestive or leading inquiries are admissible when dealing with young persons.

In this connexion—namely, employments in which there is a considerable attention required while the muscular effort is not in the usually accompanying proportion—it is interesting to note that shirt machinists in factories are in the habit of singing in unison at their work; and that employers state that they like to hear this occur, because the output of work is usually good under such conditions. There is still room for much investigation to be done under this heading, more especially to set the upper limits to "speeding-up" and if possible to devise some test or tests to determine this for each worker, for the individual variations are a source of much industrial difficulty. If the output is rated too high, the worker is sweated to make a living wage; if too low, the master may go to the wall.

Vocational Selection on a Basis of Physical Inquiry.

In the middle and working classes the choice of a vocation is conditioned by one's environment for the most part, and in a secondary way by chance. A worker hears of a vacancy in some factory for a boy or girl and reports the matter to friends who have young people about to leave school. Application is made for the post, and the foreman or manager selects or rejects the candidate according to various points which his experience has taught him. But the influence of the person recommending may cause engagement to take place in spite of obvious defects or other better material offering. The whole process is more or less haphazard. Nevertheless, it preserves the individual's freedom of choice, however little it may be exercised. It is now proposed to select the worker for the vocation on the basis of intelligence and physical tests, although in the first instance they are only to be advised "as to the occupations for which they are naturally fitted." Very great caution and circumspection will have to be exercised in this matter, the adviser bearing constantly in mind his own severe limitations of knowledge of the different aptitudes required; and moreover that a child who may fail to shine in his test scheme may nevertheless display peculiar adaptability to a branch of manufacture. The case quoted above of the child classed as mentally defective illustrates this, although one has to remember that at present such classifications are not universally reliable.

While this is so there are certain defects which are such as to demand that the individual's freedom of choice should be curtailed, in his own and the employer's and the public interest. We are here limited to the physical side. Certain broad generalizations can be laid down: the stronger and more robust should be advised to the more arduous and trying occupations; those subject to bronchial conditions should have indoor non-dusty jobs; while those with heart affections would be advised to the clerical or such-like tasks. Children of small size might still be of service in work done in the sitting posture, as the sitting height is usually good, the shortness being commonly in the legs. In this connexion it must be remembered

that such children often grow considerably for the first year or two after starting work, whether from improved feeding or other causes. Then children with serious defects of sight should be excluded from all work with moving machinery. Squint or strabismus is associated with defective sight in the squinting eye, up to practical blindness. All such cases should be carefully examined and their position definitely defined. Want of cleanliness of the head and body should be an absolute bar to all work connected with foodstuffs. It is not sufficient here that the children should be examined within a week after starting work. To have an odd child with scabies engaged in the manufacture of chocolates is bad enough, but some young persons, very dirty as to head and body, but with a surface cleanliness, are so engaged. An inspection should take place prior to engagement, and can be most efficiently done by the welfare master or mistress.

Special problems arise, such as persons with perspiring hands, with odoriferous bodies and feet, and so on. These must be settled on their merits. They will not arise as a rule in open-air jobs, but where work is carried on in enclosed spaces with increasing temperature and poor or no ventilation.

It may be said that these precautions are obvious ones. No doubt that is so to the trained observer, but we must remember that the engaging of young persons is still practically anybody's job, and that experience gained is lost to the firm when the person gaining it is promoted to another task where this is not one of his duties.

Summary.

Hours of labour: Spells of work to be normally two to three hours in all occupations demanding steady application and attention. In arduous work there must be rest spells after excessive exertions, and the latter must not be unduly prolonged.

Definite intervals for meals must be provided. For work starting before 9 a.m. two meal periods should be interposed in the time-table, owing to the fact that few persons take a normal amount of food in the morning, and it is too long to work a three or four hours spell before again getting food.

For the eight-hour day a three-spell day is therefore recommended, the first of two hours and two of three hours each. For a nine-hour day the first spell may be two and a half hours and the others three and a quarter hours each. If an industry can give a "living wage" on shorter hours this should be done, and the morning spell abolished.

Conditions of employment, especially in hazardous occupations, should be good. If such conditions cannot be secured, the industry should be suppressed.

Methods of work are worthy of study, to eliminate waste of energy, to find "best" methods, and to avoid harmful movements.

Vocational selection is at present limited to the "don'ts" department. Young persons with certain defects should not be permitted to engage in specified employments.

ADDENDUM.—Since the information in this paper was published, and as a consequence thereof, much additional information has been conveyed to me in regard to food difficulties in connexion with the morning start at 7.30 or 8 a.m. and working without a break for four, four and a half, or four and three-quarter hours. In some cases the breakfast, of whatever kind, is partaken of one hour to one and a half hours before the starting time. In an engineering works, after three years of the 8 a.m. start, numbers of the men have discovered for themselves the value of rising at 6 a.m. and leisurely making their old breakfast of porridge and milk which their wives formerly made for them at 9 a.m. This fact is a valuable confirmation of the advice given in the paper; for though tendered to many mothers during the past dozen years none have reported its adoption or the result. (D. McK.)

DISCUSSION.

Professor E. L. COLLIS (Cardiff) described fatigue as a negative term and netivity as the real subject of inquiry. Maximum activity and maximum health went hand in hand. The end and object of the doctor and the employer were really identical. Hours of labour must be distributed so as to produce maximum activity or output; health would follow. Study of industrial output showed that, as in athletics, the record-holder proceeded at a steady even pace and not by fits and starts. Schemes for hours of work must stimulate an even pace. Vocational selection to-day should be more confined to physical and physiological characters and less to the newer science of psychology. Not until the former were exhausted should psychology be appealed to.

Dr. W. F. DEARDEN (M.O.H. Port of Manchester) referred to the statement that workpeople did not get to bed sufficiently early to get the necessary night's rest, and was of opinion that this must be due to local conditions more than to daylight saving. He had himself noticed the late hours kept by Glasgow people, the streets being quite alive with promenade at 11 p.m., and these had not all disappeared at midnight. This was quite different from what obtained in Manchester and other Lancashire towns, which in the evening had more the appearance of dead cities. The last remnants of the inhabitants were on their way home at 10.30 p.m., and were at home if not in bed at 11 p.m.

Dr. McKENZIE, in reply, thanked Professor Collis and Dr. Dearden for their illuminating and kindly criticism. The suggestion thrown out by the former, that it was the steady pace that paid, was a valuable one. As to the lateness of the hour for retirement in Glasgow as compared with Manchester and other Lancashire towns, perhaps Glasgow's late car service had a deal to do with it. Late hours were certainly detrimental.

THE CONSTITUENTS OF FRESH AND VITIATED AIR AND THEIR SIGNIFICANCE IN PROBLEMS OF VENTILATION.

BY

J. P. KINLOCH, M.D., D.P.H.,

Lecturer on Public Health, University of Aberdeen.

[Abstract.]

IN view of the benefit derived from exposure to fresh air in the open as contrasted with the air of occupied rooms, it has appeared useful to investigate the value of the so-called "active oxygen." To this end a series of oxidation experiments have been devised. Cubes of phosphorus of equal surface area and equal freshness were prepared and were exposed in specially designed flasks for half an hour to atmospheres of fresh and expired air respectively, the amount of the resulting oxidation being measured in terms of phosphoric acid. Under such experimental conditions it was found that oxidation in fresh air exceeded oxidation in expired air in the proportion roughly of about 4 to 1 instead of in the proportion of 4 to 3, as might have been expected from contrasting the oxygen content of the two air samples.

The interpretation of such results is difficult. It is at once obvious that the law of mass action is not applicable to action at a surface, surface being concerned in this case and not volume. Moreover, allowance must be made for migration or diffusion of the reacting substance in the oxygen content of air towards the surface. Finally, the oxidation of phosphorus is known to present certain physical anomalies that make it impossible to arrive at a definite conclusion from the oxidation results obtained. Experiments with several other rapidly oxidizable substances failed to give proof of the presence of an especial "active oxygen" content in fresh air. It may be of interest to note that the phosphorus cubes first used in these experiments were graded and polished by file under water. It was found, however, that comparable discs of equal surface area were best prepared by moulding under hot water. It is only right that I should acknowledge here the assistance I have received from Dr. Brownlee, statistician to the Medical Research Council; he designed the initial experiments here described.

It is evident from previous experiments of other workers that the ill effects resulting from a vitiated atmosphere are not due to a diminution of oxygen or to an increase of carbon dioxide. As regards impurities in the atmosphere, the general consensus of opinion based upon the evidence presented excludes such poisonous bodies in expired breath as a factor explaining the malign effects of vitiated air. All the experiments devised to demonstrate such an effect have failed apart from the demonstration of sensitization to proteins. It is concluded, therefore, that the ill effects produced by vitiated air are due to physical changes only. The work of Leonard Hill and others makes it obvious that the vital element in ventilation problems consists in regulating the temperature, moisture, and motion of the air.

Chemical analysis having failed to demonstrate the cause of the "deadness" or want of freshness in air, and the effort to demonstrate clearly an "active oxygen" content of fresh air by means of oxidation experiments having been indefinite, it appeared that it might be of advantage to test

further the physical changes in vitiated air. In this connexion it was evident that, while the presence of radio-active substances in the air had been demonstrated by Elster Geitel, and that it was known generally that air and soil contain mineral springs contained certain radio-active substances, nevertheless the accurate measurement of the radio-active changes in the air had not been accomplished, nor any effort been directed towards determining the possible effect of such radio-active changes on biological activity. A view of the otherwise extensive and intensive investigation the physical components of air and their effect on human well-being, the investigation of the radio-active properties of air appeared to be urgently desired.

An apparatus was put at my disposal by Professor So of Oxford University in the form of an experimental electroscope of one of the types used for radio-active measurements. With such an apparatus two points may first be demonstrated—namely, (1) air washed through water in a wash bottle before being passed through the experimental air tube of electroscope is deprived of its ions, as a result of which electroscopic leak is diminished; and (2) air passed through a rubber tube before being admitted to the experimental tube is similarly deprived of its ions. It is obvious, therefore, that the modern system of artificial ventilation, wherein air is washed by passing through a water screen and thereafter conducted through a series of ducts, must deprive the air whatever ionic content it initially had. Moreover, it is further demonstrated by this experimental electroscope that expired air is destitute of ions as judged by the delay in discharge of the electroscope. It is evident, therefore, that should the ionic content of air have any benignant effect on human well-being its treatment in any modern system of artificial ventilation serves but to deprive it completely of such energy content.

It has been found that the passing of a continual stream of expired air through the tube of the experimental electroscope results in the production of a negative radio-active effect. Thus a continual stream of expired air, instead of causing slowing of the discharge of the electroscope, a result to be expected on account of its lack of ion content, although such slowing might have been compensated for by the increased leak due to the influence of condensation water which rapidly covers the under surface of the insulation of the electroscope, causes a complete arrest of electroscopic leak and results in a cessation of the leak for the period of a quarter of an hour, the duration of the experiment. The result, amounting to an increased charge on the electroscope has been continually experienced when a current of expired air has been passed through the tube of the electroscope. The existence, however, of such a thing as negative radio-activity is according to modern theory an impossibility, and the effects observed in the electroscope were attributed to instrumental or other experimental error.

In order to test for such experimental error, the following points were determined:

1. Any possibility of the result obtained being due to the nature of the original electrical charge on the electroscope was negatived by finding that the same effect always occurred, whether the charge was negative or positive.
2. Any possibility of an induced electrical charge due to the passage of the air current being the cause was negatived by earthing the tube of the electroscope.
3. Any possibility of the so-called apparent charge on the electroscope being due to any thermal currents was negatived by (a) boxing the apparatus so that the continuity of the experiment should be obtained as a cause, and (b) by enclosing the entire apparatus in an incubator constantly maintained at a temperature of 37° C.; it was found that no alteration in the results occurred under both these conditions, the apparatus continuing to record an increased charge so long as a current of expired air was passed through it, and no matter whether the electroscope had originally received a negative or positive charge.
4. Finally, it might be suggested that the increased charge shown on the leaf of the electroscope when expired air is passed directly through the tube is to be explained by the assumption that there is a diminution of the dielectric capacity of expired air as compared with fresh air. This is negatived, however, when it is recognized that the dielectric capacity of air appears whenever the air of the tube is expired. Moreover, the variation of dielectric capacity in gases such as oxygen, nitrogen, and carbon dioxide is so small, 0.0004°, that it is clearly altogether unlikely that decreased dielectric capacity of expired air is the cause of the phenomenon observed.

In connexion with the observations on my part, which are entirely independent of the work of other observers, as to the effect which expired air has on retarding the rate of discharge of the electroscope, the findings of electroscopic

retardation by two other observers are of interest. Thus Lazarus-Barlow has announced similar findings in connexion with the examination of carcinomatous and non-carcinomatous tissues. Similarly Buchner communicated on the same day to the Royal Society a paper on a mineral which retards the rate of discharge of an electro-scope. I am convinced that, similar findings having been described by three independent workers, renewed observation is urgently required. Intensive investigation of all the principles concerned in the differences between fresh and vitiated air have until now failed, and, it being the general consensus of opinion that the so-called fresh air of any artificial system of ventilation is dead, it is my opinion that the ionic differences, both physical and physiological, between fresh and vitiated air should be further investigated.

THE WRONG TURNING IN PUBLIC HEALTH.

BY

FRED. E. WYNNE, M.B., B.CH., D.P.H.,
Professor of Public Health, University of Sheffield.

THE administration of public health in its beginnings, and indeed up to quite recent times, was essentially what it was often called—"preventive medicine." That term has almost dropped out of use, and the "wrong turning" I allude to in my title is the tendency for the ideals of prevention to be obscured in our solicitude for the treatment of individuals already diseased.

Communal disease is the last term in a faulty social metabolism ; to alleviate or cure it in the individual is the function of the physician and the surgeon. To seek its origin, to discover where the social metabolism goes wrong, to direct our social evolution along the channels that make for health in the community, is the function of government, both national and municipal.

The principal cause of communal disease is poverty, and poverty is increased by waste. It is admitted that excessive taxation, both national and local, is one of the causes that is preventing trade recovery, and is thus both directly and indirectly increasing and maintaining poverty ; and, with poverty, public ill health. Every penny spent on public health administrations, as on education or any other object admirable in itself, is as much waste, if it cannot be justified by results, as if it were spent on any other form of extravagance. When Government or municipal organizations begin to deal with individuals the tendency to waste is enormously multiplied, for public funds can never deal with the whole of the individuals suffering from disease. We shall always be attacking our problems on mere fragments of the periphery, and as can already be seen the cost of this kind of skirmishing is so excessive that in these days funds must be diverted from what should be the main attack on disease at its source and origin.

This modern tendency is all to the credit of our consciences, of the emotional side of our natures. In spite of the callous delight in murder, the recrudescence of the belief in violence and destruction as a means to political ends which has disgraced the post-war period of our history, there was perhaps never so much pity for suffering, never so many consciences awake to the rights of helpless people, "of women labouring with child and young children," of the maimed and crippled and diseased, as there are in this distracted generation. Industry is no longer allowed to grind wealth out of needlessly inflicted suffering, even soldiers are cared for, and possibly merchant seamen will one day be treated as human beings when the public learns how they are treated even now. It is not very long since torture was regarded as a therapeutic measure for lunatics. Now if we hear of an asylum attendant losing his temper with a patient it is regarded as a national scandal and a Royal Commission is demanded. All these are but instances of what even the pessimist must regard as a genuine evolution proceeding in social morality. If it does lead to the formation of endless committees and innumerable so-called "national councils" for doing the same thing under slightly different names, the majority of these

organizations are quite harmless, and if they waste money it is largely money which would otherwise have been wasted on something else.

We have thus in the promotion of public health a greater backing of enthusiasm than probably our predecessors ever knew. But enthusiasm to be effective must be guided by expert criticism, and I think it is the duty of public health administrators to resist the temptation to yield to popular clamour in favour of purely eleemosynary schemes, or methods of advertisement, which tend to divert public funds from the prevention of disease to tinkering with disease when it has developed.

It is to me humiliating that the sole check on public health administration should be financial control. And of this we have recently had unpleasant though fully justified examples. The value of human health, if reckoned only in terms of money, is so immense that public opinion would not long tolerate a refusal to finance any proposal which would certainly result in a lessening of disease or an increase in the expectation of life. Unfortunately at present money is most lavishly spent in the very directions where it is least possible to demonstrate the value of the results.

The difference between these two theories of public health progress has been admirably put by Sir George Newman with his invariable instinct for the just word. Speaking to a post-graduate class for school medical officers recently, he said : "The centre of gravity of our activities that I think we should view with a certain amount of distrust, especially in these days when expenditure in new directions necessarily involves curtailment of other functions."

The principal developments in public health administration of late years have been the National Insurance Act, with its provisions for the treatment of sickness generally, and in especial of tuberculosis ; the medical inspection and treatment of school children ; the great development of maternity and child welfare work ; and lastly, the free treatment of venereal diseases.

The whole of this work, all most laudable in intention, is directed to the individual. Its cost has been almost incalculable, yet when it was found necessary to tackle the impossible environmental conditions into which our population had drifted at the termination of the war, the whole of our housing schemes broke down for want of money. Overcrowding and slum conditions are to-day engendering tuberculosis, drunkenness, venereal diseases, rickets, pneumonia, measles, and other diseased conditions in quantities which our breathless efforts at dealing with end-results are powerless to overtake.

On the other hand, public health administration of what I may call the old-fashioned sort aimed almost entirely at the environment. The improvements effected by it affected whole masses of the population, not selected individuals, although of course there was none of the cowardly callousness towards the individual which characterized ruder ages—as, for instance, in the treatment of lepers, where the suffering individual was deliberately and ruthlessly sacrificed in the interests of the rest of the community.

Public health in the sense in which we know it, including all factory and industrial legislation, is practically the product of the nineteenth century. The unexampled increase of population resulting from the industrial revolution ; the mad rush for wealth which welcomed a teeming and half-starved population as an unlimited reservoir of cheap labour in peace and cannon fodder in war ; the utter want of foresight which permitted this population to develop uncontrolled in conditions of equal almost inconceivable to us now, had its reward in the epidemics of fever and cholera which at last terrified our rulers into passing legislation directed to the serious improvement of the environment of the people. The various measures passed during the first three quarters of the century were consolidated in the Public Health Act of 1875, which has from time to time been amended, and was quickly followed by further legislation in the Infectious Diseases Prevention Act and the Housing Acts.

Every medical officer of health knows the depressing effect, the sense of almost hopelessness, that is apt to crush him in his visits to insanitary property, the indignation that is apt to possess the twentieth-century bosom in the presence of overcrowding, dilapidation, dampness, darkness, dirt, unpaved yards, privy-middens, open ash-pits, above all the acquiescence

in squalor, the indifference to filth, the utter carelessness that makes the worst of foul conditions which is displayed by a generation that is the product of over fifty years of what we retain the habit of describing as "education."

When I am most depressed after such a tour I turn to a manuscript report in my possession on the sanitary conditions of Sheffield. This report refers to the condition of the town in 1846. I learn then what were the problems our fathers had to face.

This very ably written document gives in elaborate detail the condition of yards ankle-deep in putrefying ordure from privy-middens used by from fifteen to twenty families. In this the children played and the liquid material drained into the houses. There is one case of a privy serving nineteen families and the children attending a school built over it, a frequent arrangement in those days. Everywhere in the poorer parts of the town there were rotting piles of vegetable and other refuse, unremoved except by the natural processes of decay. One court is mentioned in which the whole of the inhabitants were suffering from "low fever." People were forced to live in these places

"because of the lowness of the rents. In nearly every case we found on inquiry" (say the authors) "the people resolved to remove as soon as they were able. Too often, however, that time never arrives. From constant ill health and loss of labour their circumstances are seldom improved but become worse and worse, and if death take off the main branch of the family nothing remains for the survivors but the union workhouse."

That quotation is a very complete indictment of the principle of leaving the environment alone and dealing with individuals. The water supplied to the town is described as being of good quality, but

"the supply of water in many parts of the town is not kept up for more than two hours at a time, twice or three times a week, and this being distributed to the humbler classes by means of public stand pipes, many find great difficulty in procuring a sufficient quantity for ordinary domestic purposes, much less for scouring their houses and courts. Many persons are in the habit of storing the water in wooden tubs placed before their doors, when it soon becomes foul from the deposit of soot and other foreign matters so as to be unfit for use."

The well water is described as being freely polluted by putrid material from the conditions enumerated in the first part of the report.

Ventilation of the houses was "by apertures in doors and windows," and even these had to be kept closed owing to the abominable stench from outside. Ventilation of schools, workshops, and public buildings was quite simply ignored.

It is not surprising that in 1832 Sheffield was visited by an epidemic of cholera which caused over 400 deaths in six months, and that the normal death rate of the town at the time of this report was over 28 per 1,000.

Such were the conditions with which early public health legislation had to cope, and no one who is familiar with the Public Health Act can fail to be impressed with the comprehensive and radical ideas of the men who framed it.

In all the legislation of that period almost the only attempt to deal with the individual was the provision of isolation hospitals for infectious disease, and that was undertaken primarily not in the interest of the patient but for the protection of the community against the spread of the disease. Even vaccination, though necessarily applied to the individual, was, in the days before sanity was ousted by sentimentality, made compulsory for the whole population.

It is interesting, therefore, to glance at the results achieved by this tremendous attack on environment and to compare them with the results so far achieved by our modern method of treating the individual.

The history of the general death rate in England and Wales during the fifty-two years 1870 to 1921 shows that the highest figure was 23, in 1870. This is almost equalled in 1875, the date of the passing of the Public Health Act, and from that time on the decline has been continuous, so that in 1921 the rate is practically only one-half that of 1870—namely, 12 per 1,000, against 23 per 1,000. If it were possible to take the figures for the great towns only, this decline would be very much more marked. But populations in the great centres have altered so much during this period that accurate comparison is very difficult. Had the death rate remained during this half-century

at the 1870 figure with the progressively increasing population the number of years of human life which would have been lost is almost incalculable. It seems to me impossible to find a factor in bringing about the change which can compare in importance with the steady pressure of public health authorities in improving environment.

The history of the decline in the death rate from some of the more important infectious diseases from 1851 to 1920—a period of seventy years—shows that at all ages the death rate from the group of diseases known as "Fever" has declined from 980 to 25 per million. This group includes the exanthemata, and in the earlier decades relapsing fever and other forms of continued fever, which were not always diagnosed with accuracy. Many of these cases were probably typhus and typhoid. It is quite likely that the group includes cases which would now be classed as influenza, pneumonia, appendicitis, and other abdominal conditions not accurately understood in those days.

Small-pox, with a sudden rise in the late sixties, has declined from 250 per million to nothing; enteric from 375 in 1870 to 25, and typhus from 75 in 1870 to nothing.

In the age groups 0 to 15, the mortality from scarlet fever has declined from 2,700 in 1865 to 25 in 1919. This is without an corresponding declension in the attack rate: it is almost entirely a lessened fatality representing a change in the type of the epidemics. The only factors we know of to account for this are environmental improvements and isolation in hospital. It seems not unlikely that as the more severe cases would be more certainly diagnosed and isolated, it was the milder strains, the missed cases, that had the opportunity of propagating a milder type of the disease.

Diphtheria has declined from 1,400 in 1865 to 500. Here, of course, an important factor has been the introduction of anti-toxin, essentially an example of treatment of the individual, but the high death rate from this cause remains an unsatisfactory feature of our statistics.

Measles, for which nothing has been done directly, has hardly declined at all. The comparatively low figure of 600 in 1919 has no guarantee of permanency, and measles remains the most deadly disease of infancy; all the more dangerous because it seems impossible to teach the public that it is not a trifling disease, although even in the sixties it was claiming nearly five times as many victims as small-pox.

These are records of great achievement, and it would, of course, be unfair to expect the curve of progress to maintain the same steep angle. It is also impossible to make a just comparison between recent developments, with a record of only a few years, and the comparatively long periods we have been discussing.

In the decline in infant mortality from 1870 to the present day what I may call the individualist school of public health has its greatest triumph. Investigation shows that all the sanitary work of the last thirty years of the nineteenth century did nothing at all to protect or prolong infant life; in fact, during this period it actually reached its maximum in 1890. This is not very surprising, for the child's environment is its mother or its nurse, and to this day hygiene and mother-craft are not considered "educational subjects." The management of infants remained a matter of tradition expounded by the handy woman and her colleague the lady next door.

Doctors who seldom saw a sick baby before they were qualified absorbed their clinical teaching from the same exalted source. Convinced that Nature did not know how to make a baby that would not come unstuck after it was born, they continued to compress ribs and abdomen with flannel binders, to deprive the child of Nature's colostrum, to dose it with indigestible starch in the form of barley water; when the child got indigestion accordingly they repeated the midwives' dictum that it was "sucking wind," and acquired a reputation for practical wisdom and being a "very clever doctor." Then of course the child had to swallow drugs of one sort or another, or wherewithal could the quarterly bill be furnished forth? Then when the child was weaned, prematurely or otherwise, the only available food was the emulsion of cow-dung and house-flies known as fresh milk.

Our child welfare centres have done an immense amount to change this state of affairs. To them and their staffs, and to the unremitting toil and devotion of armies of health visitors, must, I think, be given the main credit for the fact that the

infantile mortality of England and Wales in 1921 was almost precisely half what it was in 1899.

But mere saving of child life is not enough as an end, unless we make these lives worth living; and I do not believe that life in a slum on the margin of subsistence is worth living. I think most of us, if we had to be born again as a slum child, knowing what we know now of the prospect before us, would say "an enemy hath done this thing," and desire greatly to be put to death before the weary pilgrimage began. The very fact that we are causing so many infants to survive seems to me only to emphasize the duty of providing them with an environment in which they can be happy.

The story of the death rate from pulmonary and other forms of tuberculosis from 1859 to the present shows very clearly the seldom appreciated fact that tuberculosis was a steadily decreasing disease for at least a generation before the public became excited about it. I think it is probable that the apparent reduction in mortality is to some extent neutralized by increased accuracy in diagnosis. This, however, is a factor which cannot be demonstrated, but must be assumed, so that in all probability the progressive decline is even more marked than would at first appear. There was a temporary interruption of the decline during the years 1915 to 1918, but I do not think it would be fair to attribute this increase entirely to the introduction of sanatorium benefit. War conditions and pensions claims increased both incidence and notification, and a change in public opinion had removed the desire for concealment of the true cause of death. Phthisis, in fact, became much more remunerative as a cause of disablement than chronic bronchitis or emphysema. At the same time I have no doubt, having personally witnessed its effect, that the system of three months' treatment in a hospital or sanatorium of infective cases, by slightly prolonging the lives of the sufferers, increased their opportunity of disseminating the disease when returned to "domiciliary treatment," and that this tendency was not neutralized by any training or discipline which was inculcated in the hospital. The whole of our tuberculosis administration is in fact a classic example of the ill effects of neglecting environment in favour of dealing with the individual. Well-intentioned but untrained people awoke to the fact that very large numbers were dying of tuberculosis, and about the same time open-air treatment and sanatoriums were boomed as a method of cure. There was an outbreak of "national societies" through which influential members of society demanded the immediate provision of sanatoriums for all, and this to a great extent was done at an enormous cost in the days when there was "money to burn."

The thing must be done on a "national" scale; there was to be no waiting for the result of experiment on a smaller scale, and the still small voice of criticism and warning was ignored. But the warning voice was there. Many who had long experience of tuberculosis were sceptical, and as long ago as 1910, when the Insurance Bill was still under discussion, Messrs. Elderton and Paten had published the third series of their *Study of the Statistics of the Mortality of the Tuberculous and Sanatorium Treatment*, under the auspices of the Department of Applied Mathematics of London University. Their conclusions were as follows:

1. The mortality of tuberculous patients who are undergoing or have undergone treatment is much heavier than that of the general population, and even when the disease is taken in an incipient stage the mortality is about four times as heavy.
2. The mortality of the apparently cured cases is about twice as heavy as that of the general population.
3. The mortality among sanatorium patients does not show any improvement on that of Williams and Pollock's cases—that is, cases treated in pre-sanatorium days.

These conclusions are fully borne out by the more recent statistics of Dr. Bardswell and others, and I think it is now commonly held that the most hopeful function of the sanatorium is the isolation of infective cases. Yet we have been landed in the position of spending some millions a year on the treatment of tuberculosis, while there is no money available for the elimination of the insanitary areas where we cultivate more tuberculosis in a week than all the sanatoriums could house in a year.

This is largely due to the eleemosynary idea, admirable in itself, but cruel in its results. In my experience hard heads contain more real kindness than soft hearts. Improved sanitation has helped the natural tendency to the elimination of tuberculosis which statistics prove to be in operation. The only

practical sanatorium for the people is a reasonably healthy environment in their own homes. It is on the people themselves that the cost of all this business eventually, if indirectly, falls, and by increasing poverty we are creating more disease than we relieve.

I must now refer briefly to that very important branch of modern public health work—the school medical service. Here again I speak from an experience of over ten years as a school medical officer, and I am satisfied that as a result of the work of the school medical service a very large number of individuals has been benefited. We have only to read through Sir George Newman's most valuable reports to realize the vast scale on which the work is now organized, a development of which some measure may be found in the fact that the cost of the service has increased from £325,735 in 1913 to £885,625 in 1920.

Even the latter figure would be by no means excessive if it were producing a harvest of health, if it were being spent in directions which could be relied on to produce successive crops of school children with a declining sickness rate, so that the cost of discovering and treating ailments would be a steadily diminishing amount. But among all the tables published in these annual reports I can find none that shows a comparison between the percentage of children found to be suffering from some form of defect in each of the years since school medical inspection has been in force. The materials for such a table must be available, but there is no reason to suppose that it would show any decline. The number of cases of disease treated in one generation of school children will not lessen the number of defects in the next.

The best test of the educational success of the school medical service is probably the promotion of personal cleanliness and the reduction of verminous conditions. In the ten years' retrospect included in his 1917 report Sir George Newman claims that ten years' work has "revolutionized this matter," and in support of this statement he is able to quote some very remarkable achievements in London, Torquay, and Carlisle. But the comparison is not given for the whole country. In the districts with which I have been familiar, while there has been some improvement it has been much less marked. And the improvement has been something imposed upon the parents by the authority, not emanating from themselves, and therefore not indicating an advance in civilization.

The diagnosis of vermin is still met by parents as an insult, and denied even in the face of the demonstration of lice actively parading the scalp. I was once assured that the child could only have obtained these companions from myself. It is scarcely surprising that we are still confronted by the parent who admits the presence of "nits" but assures us that there is "nothing living," since this extraordinary distinction is apparently official and is retained in the annual reports. What would we think of a sanitary inspector who reported "eggs" as being present on one farm and "eggs and hens" on another? Personally I should consider that his powers of observation did not justify his retention on my staff.

At the date of this report Sir George was evidently deeply impressed with the importance of environment. He says:

"Here is an unclean child to be cleansed by the authority, but it returns to a verminous home. Here is a child provided with spectacles, but it continues to be taught to read small type in a badly lighted classroom." Here is a scheme for providing school meals, but the arrangement bears no relation to the food supply of the home of the child or the social condition in which the child lives."

Again he says:

"It is well to cure ringworm, remove adenoids, and correct defective vision; but it is still more important by unity of effort and co-ordination of agency to secure the essentials of health for the whole body of the six million children in the State schools."

Yet in 1920 he tells us, "The school medical service finds its fulfilment only in the service it can render to the individual child."

It is only a few months ago that I had to protest in vain against the continued use of a school where the only playground for boys was an underground space between the foundations of the building. On a bright summer day there was only the light available from some narrow dirt-encrusted windows on the level of the adjoining footpath, and into this space both urinals and water-closets ventilated direct. I was told that it was impossible to close the school because there was no other accommodation for the children, and as to making improvement

was a "non-provided" or denominational school, and the managers had no funds. That, of course, is typical of hundreds of schools all over the country. If the millions that have been spent on medical inspection and treatment had been spent on knocking these places down and building decent schools, schools comparable to the modern admirable "Council schools," we would then have had some right to start curing ailments as they arose. As it is we compel thousands of our children to spend a quarter of their childhood under conditions of sanitation which if permitted in a prison would set every sentimentalist in the country howling with indignation.

There is no reference in the annual reports of the chief medical officer to the sanitary conditions of existing schools, for the simple reason that no reference to this painful subject is made in the individual reports of the school medical officers; and I know why. I once published an accurate survey of the sanitary conditions of the schools in my area. I was young then and did not understand the mentality of our "educationists." But I never did it again, and would advise my colleagues to postpone any such report until they are on the eve of resigning their appointment. Perhaps the National Union of Teachers is strong enough to take the matter up in the interests of its own members as well as of their pupils. Personally I hold that the time has gone by when children should be forced into utterly insanitary surroundings in the interest either of sectarian religion or the process described as education, and to give "instruction in hygiene" under such circumstances is merely a cynical farce. It is the old story of deliberately creating disease and establishing costly methods of treating it. If the treatment is carried out by a State service it is "preventive," presumably if done by the general practitioners it does not deserve this label.

Time forbids anything but a passing reference to our latest and probably our least successful "stunt"—the campaign against venereal disease, on which we are now spending, I believe, a little short of a million a year, but it is difficult to obtain anything like accurate figures. Professor Robertson of Birmingham has rightly protested against the statement that 10 per cent. of the population were suffering from venereal disease. This estimate, solemnly adopted by a Royal Commission, was made when there were no data available for making any estimate at all, and it is obviously contrary to common experience. Practical preventive measures are objected to by those who regard the fear of disease as in some way a buttress of morality, so we spend our money on a method of treatment which we are now told is not effective unless the patient is kept under observation for at least two years. It therefore differs from the old-fashioned treatment by mercury and iodides only in being more troublesome, more costly, and more dangerous. These were the diseases for the cure of which patients were most willing to pay, but now the taxpayer must meet the bill in order to minimize a risk which very few incur except deliberately. Now that venereal disease has become a fashionable topic for drawing-room conversation, it is surely time that we pulled our head out of the sand, adopted compulsory notification, and made the subjects of disease pay for their treatment according to their means. Here again we preach a conventional morality to people for whom we have made marriage a practical impossibility by the promotion of poverty and the failure to provide economic housing.

My conclusion from all these considerations is that we have turned away from the ideals of the Public Health Act, from the improvement of environment which produced such incontestably good results, long before work in this direction was completed—when, in fact, it was little more than begun—and that we are depleting the funds required for this work by a costly and partial treatment of the end-results of the processes inaugurated by faulty environment; that we are bleeding the taxpayer and the ratepayer by expenditure that does not give an adequate return in improved health and prolonged life; that we are undermining responsibility by providing services at the public expense which should be paid for by the individual, and incidentally depriving the private practitioner of a large part of his legitimate opportunity of exercising his calling.

DISCUSSION.

Dr. MEREDITH SANDERSON (Sanitation Officer, Nyasaland) commented upon the fact that often the greatest public health benefits resulted from the use of some simple and inexpensive

measure applied at an opportune time. As an illustration he described how he had dealt successfully with widespread ankylostomiasis in his district by the installation of pit latrines that were carefully supervised.

Dr. HAROLD KERR (M.O.H. Newcastle-upon-Tyne) admitted that Dr. Wynne's contribution contained much truth, but it was tinged with bile. Newspaper "stunts" were of some value in so far as they were indicative of public interest in health subjects. All medical officers of health suffered at times from the misdirected efforts of amateur enthusiasts, but the fault lay with the medical profession in passively maintaining a vested interest in established disease. An infusion of the principles of preventive medicine into the profession at large would counteract this tendency. He advocated well-organized propaganda—such as was found in the chief health departments in America—as a means of educating public opinion in the essentials of hygiene.

Dr. W. W. KING (Public Health Service, U.S.A.) deprecated the pessimistic view of public health. Imagination was necessary to see things from a future standpoint. Present-day public health work was open to the charge of being too individualistic, but then it was only in the swaddling-clothes stage. Improvement in environment was necessary to correct the disabilities it produced in infants, school children, and factory workers. The facts could only be obtained by a study of the individual. When the conditions were known the methods of prevention could easily be determined.

Dr. ELIZABETH BELL (Belfast) and Dr. ELLINGWORTH (Melbourne) also took part in the discussion, after which Dr. WYNN: replied to the effect that we should pay more attention to relative values in public health, and not strive after the perfection of particular branches to the exclusion of fundamental aims.

A CONSIDERATION OF METHODS OF SEWAGE DISPOSAL IN THE TROPICS,

WITH SPECIAL REFERENCE TO HELMINTH INFECTION.

BY

M. KHALIL, M.D., PH.D., D.P.H., D.T.M. AND H.

(From the Helminthological Department of the London School of Tropical Medicine.)

[Abstract.]

DURING the recent expedition to British Guiana from the London School of Tropical Medicine the helminthological aspects of sewage disposal were investigated. The inhabited part of British Guiana is a primitive country, lying for the most part below sea-level and without any organized general sanitary system. In certain of the towns and villages the following methods of sewage disposal have been introduced: (1) pit latrines, (2) pail closets, (3) latrines erected on drainage trenches, and (4) septic tanks. Dr. Khalil described the different methods and discussed them from the point of view of helminth infection. He discovered that hookworm ova are not destroyed by these methods and subsequently continue their normal development. He arrived at the following conclusions:

Sewage disposal has been considered in England and Europe chiefly from the point of view of bacterial infection, particularly as regards the enteric group of organisms. The protozoal and helminthic infections propagated by faecal contamination have received no attention. In textbooks on sanitation and hygiene the protozoal parasites of man are dismissed in a few lines, mostly incorrect, and copied from one edition to the next without keeping pace with the rapid progress in tropical medicine. There is a tendency in England to dissociate sanitation and hygiene of warm climates from that of cold climates. With the facilities of communications now available this distinction is unjustifiable. Tropical diseases are being introduced into colder climates and vice versa. Moreover, this country contributes a high percentage of the medical men and sanitarians located throughout the tropics. They are apt to copy what is done or what they were taught in England, neglecting the new factors appearing in their new environments. It is not surprising that in British Guiana and elsewhere sanitarians have diligently made cultures to isolate *B. typhosus* and other organisms from drinking water and sewage effluent, and were totally unconscious of the presence of the comparatively gigantic ova of hookworm and other parasites. In tropical countries the

disasters brought about by hookworm disease often surpass those due to bacterial infections. Hookworm disease retards the development of children, handicaps their mental capacity, deteriorates the value of adult manual labour, predisposes the community to various diseases, and in addition claims a grave toll of mortality. It is not to be concluded that bacterial investigation of water and sewage is unimportant, but it is claimed that protozoal and cutozoal infections must receive due attention as well.

Bacterial purification of sewage is apparently inefficient as regards Helminth ova. It is unjustifiable to turn the effluent from such installations into rivers or canals which are used for drinking purposes, as is the routine in England. It should be kept in mind that filtration is inefficient in excluding hookworm larvae, which are capable of passing through several layers of filter paper and can penetrate the human skin. Sewage farms ought not to be encouraged in the tropics as they act as veritable concentrated cultures of hookworm larvae. One cannot wholly condemn these methods of sewage disposal, because so far there is nothing better to replace them. It is only urged that their limitations must be kept in mind till further research and observations rectify their defects.

SHOULD WE LONGER TOLERATE THE POLLUTION
OF THE AIR?

BY

EX-BAILIE W. B. SMITH, O.B.E.,

Glasgow.

THERE are many reasons why we should not tolerate any longer the pollution of the atmosphere. The most important of them all is the one specially suitable for your consideration as medical men, and that is the effect on health and life of living in air polluted by smoke and noxious vapours.

Many people seem not to realize that we are constantly passing air through our bodies; breathing goes on so automatically that we forget that we pass through our lungs about 516 cubic feet of air, weighing 38½ lb., per diem. We are conscious of taking solid food and liquid—probably about 6½ lb. weight per diem—and we take great precautions against them being in the least degree impure or contaminated. We have the Food and Drugs Act in operation and our water supply is under strict supervision. We select for use only water that is pure enough to be safe; contaminated water is not allowed to get into the mains. But we have only one supply of air; we cannot get air from any other source, or even filter it; we must breathe what is around us wherever we happen to be, no matter what its impurity or condition.

Many theoretical opinions have been given about the effect of smoky air on health. I have heard it stated that it causes no injury to health; some have even asserted that it is a benefit, because a smoky atmosphere acts as a disinfectant. We know that sulphurous acid is a disinfectant, and would be quite good if it could be sprayed on where it is wanted; but these people forget that we have to inhale this disinfectant, and that its presence in the bronchial region and lungs is irritating and harmful, just as inhaling or swallowing any other disinfectant would be. An atmosphere of chlorine would be a more powerful disinfectant, but it would be still more harmful to inhale; in fact, we may say generally that the more powerful a disinfectant is, the more deadly it would be if taken into the body, either by the lungs or stomach.

But I prefer to take practice rather than theory, and to illustrate the effect on health I will take one of the worst examples I have experienced. This was a most extreme case, but the same thing goes on in a lesser degree every winter, in every town in Great Britain, but not in some other countries.

In Glasgow, during the winter of 1909, we had a series of exceptionally bad fogs; we have had nothing like them since, and I hope we never will. It is usually very difficult to get a true standard of comparison in such matters, but I claim that I have it here. The Registrar-General, in his returns, forms a group of the eight principal towns in Scotland; they are Glasgow, Edinburgh, Dundee, Aberdeen, Paisley, Leith, Greenock, and

Perth. The population of Glasgow at that time was estimated by the Registrar-General at 872,021, and that of the other seven towns combined at 993,550. In all but one of these towns the conditions are practically alike: they are planned and built in the same style; they have about the same proportion of crowd and even slum areas; they have good water supplies, similar systems of sanitation, the same forms of control and inspection; the methods of heating and cooking are similar; and the general habits of their inhabitants are very much alike. Even the working conditions are comparable, as most of the industries in Glasgow are also carried on in one or more of the other seven towns. But their geographical positions make it improbable that they all should have quite the same conditions of atmosphere at the same time. A glance at the map will show this—three are on the west, two on the east, and three north-easterly; five are on the coast, and three are inland. A drift of air from the east will carry smoke over some while it carries it away from others; from the west it will pollute some and clear others. I have made no comparisons with rural or semi-rural areas, because many of their conditions vary from the large towns.

I remember reading what the late Dr. Russell, Medical Officer of Health for Glasgow, once said: "That during winter every city was in danger of a catastrophe if certain weather conditions occurred—a combination of keen frost, fog, and a still air for days together." Having experienced that condition, I got the Registrar-General's returns as soon as published and studied them; I compared them with the atmospheric condition in Glasgow as I had noted it day by day, checking it with the meteorological records, and I submit them for your consideration.

During the summer of 1909 in Glasgow we reached the lowest death rate recorded up till that time—about 11 per 1,000. It rose a little as the winter came on; for the five weeks ending October 30th the weekly average number of deaths from all causes was 223, equal to 13.4 per 1,000 per annum; and for the other seven towns the number was 233, equal to a rate of 12.2 per 1,000.

On October 30th and 31st we had a fog, and for that week, ending November 6th, the number of deaths was 304—equal to 18.2 per 1,000—while the rate for the other seven towns was only 12.7. The following week, ending November 13th, the Glasgow rate remained at 18 per 1,000, the other seven towns rising to 13.9.

From November 15th to 19th we had one of the worst fogs I remember, and for the week ending November 20th the number of deaths was 416—equal to 24.9 per 1,000—while for the other seven towns it was 15.3. For the following week, ending November 27th, Glasgow had 547 deaths—equal to 32.7 per 1,000—while the other seven towns were 16.7 per 1,000. During the week ending December 4th the Glasgow death rate dropped to 27.3 per 1,000, the rate for the other seven towns rising to 17.8; but during the following week, on December 6th, 7th, and 8th, Glasgow had another fog, and for this week, ending December 11th, the number of deaths in Glasgow rose to 529—equal to 31.7 per 1,000—while in the other seven towns it fell to 16.7. From then it began to decline in Glasgow, but increased in the other seven towns.

The next point was to see what class of diseases had caused this abnormal increase of deaths, and it was found that those affecting the respiratory organs, called bronchial diseases, including bronchitis, pneumonia, and pleurisy, were accountable for most of it. [The speaker showed a diagram which indicated that the increase of deaths was caused by the diseases of the organs principally liable to injury by impure air.] No doubt cold caused an increase in deaths from these causes, but that applied even more to the other seven towns, where the temperature was slightly lower than in Glasgow, but there was something more than cold, and as every other condition was similar except the impurity of the atmosphere, I am convinced that was the cause.

After increasing the Glasgow death rate for November and December above the October rate in the same proportion as the other seven towns, there was still an excess over that increase of about 1,000 actual deaths, and those were mostly among the very young and the old; these excess deaths I attribute to the impure atmosphere that the population of Glasgow were compelled to breathe. This was an extreme example, but it indicates what occurs in a lesser degree in any district whenever

the air is polluted, and probably the death rate from bronchial diseases in excess of that due to cold and damp will be in almost direct ratio to the amount of impurity. I have said nothing about the effect on phthisis or other forms of tuberculosis; owing to the lingering nature of this disease weekly or even monthly returns would be unsuitable for comparison.

If that was the death rate, what must the case rate have been? Your experience will tell you for each death how many cases of illness there probably were that caused suffering and distress but did not end fatally. Then there is the injury caused by the absence of direct sunlight and the weakening of the actinic properties of light.

Why do we continue to tolerate such a condition of atmosphere that injures and kills so many? Partly because there being nothing conspicuous or dramatic about its effects we hardly realize the connexion between the cause and the effect. If a chimney stack occasionally fell down and killed a few people we would immediately get laws passed that none but steel chimneys should be erected, and that they should be so efficiently stayed that a fall would be impossible. Partly also because we do not realize our own individual responsibility. Most people say, "somebody should do something," but many of those who shout the loudest do nothing themselves.

From whence does most of this death-dealing smoke come? Very largely from the chimneys in our own houses, offices, warehouses, hotels, etc., wherever raw coal is burned in a kitchen range or open grate of the domestic type. Even in most manufacturing towns more smoke comes from the domestic chimneys than from the factories. In Glasgow in winter time as much as 70 to 80 per cent. of smoke is domestic, except when the wind is east and smoke from the Lanarkshire "black country" is blown over the city.

We have laws to prevent factory smoke, though by many local authorities they are not put into operation and never by the Ministry of Health; but we have no powers to take action against domestic smoke, and there you can help us. Your profession takes you into the houses of all classes of our people and you have their confidence, so that suggestions and advice from you carry more weight than from others.

Fortunately we have now methods of cooking and heating that are smokeless, more convenient, save labour, and are not more costly, sometimes even cheaper, than the old-fashioned cooking range and open grate. In the construction of all new buildings, whether factories, warehouses, offices, or dwellings, all smokeless methods cost less to install than the old smoky methods.

To change over from old conditions to new does entail some expense; new fittings and their installation have to be paid for; but even then the saving of labour and the curtailment of other expenses, with the increase of convenience and cleanliness, in time will repay the outlay. In most existing buildings one hesitates to recommend putting in an installation of central heating, although electricity

is more easily installed without much trouble and at a fairly moderate cost, and with reasonable care economical in use. The greatest obstacles to change are apathy and prejudice. The public generally regard attempts to improve anything as hopeless and they want to be let alone.

Against the use of gas there has been a strong prejudice in the minds of many—a prejudice now without reason. In the earliest forms of gas fires, and in their indiscriminate adoption, there were some grounds for complaint. In many instances, where a coal grate did not do well, owing to some defect in the chimney causing the smoke to come into the room, a gas fire was put in because there was no smoke from it, but as the products from combustion came into the room, the gas fire was blamed and not the chimney. Then gas fires were put into fireplaces where the area of the chimney was far too large. The flue from a coal fireplace was made much larger than was actually necessary to carry off the products of combustion, because room had to be left for a considerable amount of soot to deposit on the sides without quickly choking up the flue and curtailing too much its area, so that it would not require to be swept at too frequent intervals. Such a flue area is too large for a coal fire under normal conditions, and is one cause of down draught, especially when a fire is being kindled, owing to the weight of the column of cold air in the flue chilling and pressing back the small volume of warm air trying to rise. A proof of this is that

nearly all cases of blowing down of smoke are caused by putting on the top of the chimney a galvanized iron "narrowing can" to curtail the draught.

When a gas fire is put in place of a coal grate, the top of the chimney should be narrowed to a diameter that will allow all the air in the room to be changed about four times an hour, which is quite sufficient for ventilation. A coal fire usually passes enough to change the air about ten times an hour, much more than is necessary, causing draughts and even lowering the temperature in some parts of a room, between the door or window and the fireplace.

To ascertain if there were any grounds for prejudice against gas fires, the Corporation of Glasgow, in 1908, instructed Mr. Harris, the corporation chemist, Mr. Fyfe, chief sanitary inspector, and Mr. Wilson, gas engineer, to investigate and report. Under their direction, in two houses similar in every respect, a long series of tests were made with a coal fire in one and a gas fire in the other, which proved that a gas fire was as healthy in the house as a coal fire; that it did not "dry the air," but that the humidity of the air in each room was practically the same; that fumes did not come into the room in one case more than in the other. That after lighting, the temperature rose much more quickly in the gas-fired room and remained constant and under complete control, while in the coal-fired room it fluctuated considerably and was not under control. They found that with a coal fire "at least 75 per cent. of the total heat generated by the combustion of coal in an ordinary fire is lost in the form of flue heat"—that is, at least 75 per cent. of the heat went up the chimney, only 25 per cent. being radiated into the room. With a good gas fire 26 per cent. of the heat generated went up the chimney, 74 per cent. going into the room. Since then improved forms of gas fires lose still less heat up the chimney and radiate more into the room. As to cost, they said:

"We are of opinion that, even when fires are required for continuous daily use, if gas is burned in properly constructed grates or stoves, and the cost of service for attending coal fires, and the extra work entailed in dusting, sweeping, and washing because of them, are added to the price of the fuel, the cost of heating by gas compares very favourably with the cost of heating by coal. When domestic cooking alone is the consideration, or when rooms require to be rapidly heated and kept at an even temperature for short periods, gas fires are not only more convenient, but will cost less than coal fires, even with gas at its present price."

As to the effect on the atmosphere Mr. Harris's analysis of the flue gases proved that over 5 per cent. of the coal used passed up the chimney into the air as solid impurities, consisting of:

Mineral matter	22.0 per cent.
Carbonaceous matter	41.1 "
Oily hydrocarbons	36.9 "

"These impurities are most objectionable, as besides being conducive to the formation of that abomination—black fog—they retard its dispersion, because on a reduction of atmospheric temperature they are condensed and precipitated with the accompanying moisture, forming an oily envelope surrounding the globules of condensed water, which prevents evaporation to a very considerable extent."

They concluded the report by saying:

"We feel assured that, after a careful study of the facts and figures herein presented, the citizens will readily acknowledge that the smoke-producing, wasteful domestic coal fire must be replaced by the more cleanly, evenly, and healthy gas fire before we can hope to obtain a purer atmosphere, or even begin in earnest with the work of air purification."

Then we have electricity, which now has become quite practicable for domestic purposes, and, used intelligently, is quite economical for cooking and heating. One of its advantages in a house is its adaptability. It can be used for cooking, warming rooms, doing the washing and ironing, running the vacuum cleaner, and driving the sewing machine. Electric radiators can be placed anywhere as no flues are required; it is not necessary to warm the whole of the room, the radiator can be placed just beside one so that anywhere in the room one may be "sitting at the fireside."

In many places, unfortunately, the charge for current is still too high. In Glasgow we find it pays the electricity department

to sell current to domestic consumers—who are paying 4½d. a unit for lighting—at the rate of 1d. a unit for all other purposes, because for these uses it is generally taken at hours of the day when we have plenty of current to spare; very little is wanted when the lighting load is on.

No one can know better than you the advantages of gas or electric heating in cases of illness—a constant source of heat, day and night if required, with the temperature under control; the patients not disturbed and the attention of the attendants not taken up by frequently putting on coal and removing ashes; no danger of causing a down draught by having the window open or closed as desired.

As there are so many advantages that smokeless methods in the house possess over the old dirty coal fires, possibly compulsory legislation may not be required—the change may come of itself without compulsion.

As regards industrial smoke, there is a constant change over to smokeless methods because they are more efficient and more economical. Now it does not pay a manufacturer to produce his own power, to have his own hoiler, chimney, engine, and all the necessary shafting and belting to carry the power through the factory, and the whole kept running when perhaps only a few of the machines are actually working. These can be dispensed with, and the room they occupy saved, the power being led through the factory by a pair of thin wires and applied by a small motor attached to each machine or tool, and current only used while that machine is in use. This also results in a great saving of coal; our electricity department can supply at the factory one horse-power for one hour with a consumption of less than 1½ lb. of coal; a boiler and engine in a factory would use three to four times this amount of coal per horse-power. But there is need for more stringent legislation and for more compulsion on local authorities to use the powers they already possess.

There are Acts of Parliament making it an offence to emit smoke from factories, etc., but they contain many defects and some of them are difficult to put into operation, and very many local authorities absolutely refuse to take any action to enforce them. So much has this been the case that it has been recommended in the Report of the Departmental Committee on Smoke and Noxious Vapours Abatement, that the Minister of Health should be given clearly defined powers to compel a local authority to take action against offenders, and failing their taking action the Minister of Health should take the necessary action.

It was clearly proved in the evidence given to that committee that nearly all industrial smoke was unnecessary and wasteful, and could be avoided. There are a very few processes in which the presence of a certain amount of smoke is necessary, such as rolling thin sheet steel, or where a reducing flame is necessary to prevent oxidation. In such cases, I recommended "that the Government should stimulate and if necessary subsidize research with a view to discovering an efficient method of catching or consuming the smoke before it passes into the atmosphere. When such a method is found, its adoption by manufacturers should be made compulsory, and local authorities should be empowered to make a contribution, if they desired, towards the cost of installation and its maintenance."

If it could be shown that in any process it would add to the cost of production to treat the smoke and prevent it getting out into the atmosphere, I am of opinion that the cost of so treating the smoke should be paid to the manufacturers out of the health rate of the area in which the works were situated. The chances of having to make any payment are remote, and could only occur in a very few cases throughout the whole country; and even then the amount would be small. With the exception of certain operations in steel workings, all the evidence has proved that methods that prevented smoke saved money to the manufacturers. To quote one instance of this: We were told by certain witnesses that in making and glazing certain kinds of pottery ware it was impossible to fire it without making a great amount of smoke; that gas was not suitable for firing such articles; yet, within a few hours of hearing that evidence, we saw the firing being done with gas quite successfully and with a considerable saving in the cost of fuel.

We in Glasgow spent a capital sum of about 2½ millions and a charge of £300,000 a year on our sewage purification scheme that we might have a clean river, and we spend annually in the health department about £750,000 to prevent illness by the spread of infection; therefore it seems to me reasonable that

a community might pay a little to prevent illness and improve the amenity of their district by preventing any pollution of the air by smoke and noxious vapours, should such a contribution be necessary.

If other cities and towns care to continue to wallow in a filthy atmosphere, their improvement seems rather hopeless. We in Glasgow have decided that we will not do so; we are doing all we can to make our atmosphere clean, and we are going to insist that our near neighbours shall not be allowed to send pollution into the air that is carried from them over our city—air that we have to breathe and live in.

DISCUSSION ON.

Professor LEONARD HILL initiated the discussion by stating that smoke abatement should be one of the fundamental objects of public health. From every point of view a smoke-laden atmosphere was detrimental. The presence of smoke indicated excessive waste of thermal energy. A comparison of thermal units used in the ultimate production of electric light from burning coal and those expended by a glow-worm showed how very far this country was from the economy of nature. Distillation of coal on a grand scale would save the valuable by-products and still produce sufficient thermal units for manufacturing and heating. Smoke caused fog, and fog caused delay, annoyance, and financial loss, as well as loss of health. It destroyed vegetation in the neighbourhood of towns where it was most needed; it shut off sunshine in the places where it was most necessary; its effect generally was depressing and lowering; it was unnecessary, and, most important of all, preventable.

Dr. T. M. LEGGE (Home Office), in undertaking a partial defence of the smoke bogy, protested against the lack of a sense of proportion in this indictment of the smoke nuisance. There was a "stunt" just now in favour of the gas fire against the open fire. The open fire meant a free current of air in the living room, and he could imagine nothing more unwholesome or disgusting than the smell of cooking from the gas stoves installed nowadays in almost every little tenement. Coal was essential to most metallurgical processes, and the pall of smoke which lay over manufacturing towns was a monument to man's industry and his triumph over matter. He was not in favour of substituting gas for coal in heating. Gas supplied for this purpose was highly dangerous on account of the carbon monoxide it contained, and deaths from gas poisoning were occurring with The smoke problem had gradually grown of industry, and could not be instantly abolished.

Ex-Bailie SMITH, in reply, said the speakers had left him little room for reply. He had studied this question for a long time, and was absolutely convinced that smoke did far more harm than was realized. He hoped everyone in his own district would do a little to "clear the air."

DISCUSSION ON

THE TRAINING FOR THE D.P.H. AND THE NEW REGULATIONS.

OPENING PAPER

BY

EDWARD W. HOPE, O.B.E., M.D. EDIN.,

D.Sc. (Pub. Health),

Professor of Public Health, University of Liverpool.

Prior to the passing of the rules which will in due course become operative, certain observations were submitted by me from which it will be seen that the broad general lines decided upon were in my view necessary.

I have had an experience, extending over a great many years, of the teaching of the subject of public health, and the course of instruction in Liverpool has been modified and moulded upon such lines as are calculated to meet the needs of the modern medical officer of health.

As a present or past examiner in the subject in various universities—namely: Liverpool, Manchester, Belfast, Cambridge, Edinburgh—and at the examination of the Royal College of Physicians of London and the Royal College of

Surgeons of England I have been impressed with the fact that, either from lack of opportunity or want of attention on the part of the candidate, he or she is frequently deficient on matters more or less essential, of which, given the opportunity and reasonable diligence, a full knowledge might have been acquired.

The existing regulations of the General Medical Council are themselves revisions and advances upon those first called into operation, and I am of opinion that, in so far as they relate to the two important subjects of chemistry and bacteriology as applied to public health administration, they do not call for change. These courses are short—namely, three months for each—and consequently they do not make a great demand upon the time of the candidate. I fully recognize that the medical officer of health has in almost every case the opportunity to consult with those upon whom the duty of chemical analysis and bacteriological examination falls, but notwithstanding that, it is in my view an incalculable benefit to the medical officer if he has acquired a sufficient knowledge of these subjects to enable him to appreciate the methods and results. It is quite likely, however, that some modifications in the examination may be thought desirable.

The modern medical officer of health is most concerned with practical administrative details, and with the methods of application of various Acts of Parliament and the numerous orders of the Ministry of Health, and of the various Government departments designed with a view to improve the public health. It is with the daily application of these that the medical officer of health to-day is chiefly interested, and the curriculum should afford to every candidate opportunities, full and varied, to become practically familiar with them.

In my view, the time allocated—namely, six months—is sufficient for the purpose, notwithstanding that either chemistry or bacteriology may be taken during part of this period. The difficulty, however, consists in the lack of opportunity at some of the districts in which the student may be placed. At present the population basis alone is taken as a criterion of adequate teaching equipment, without regard to the fact that a population of 50,000 may be, and frequently is, so happily placed as to render active sanitary operations unnecessary, whilst other examples are not far to seek where a very partial sanitary equipment appears to meet local needs. The consequence is that many candidates are received for instruction in localities with very limited scope for training, and the conditions are widely different from those districts in which the maintenance of the public health presents constant and insistent demands. I would suggest, therefore, that, if a population basis is retained, it should only be on condition that adequate opportunities for training are available to the entire satisfaction of the Public Health Committee of the General Medical Council. Alternatively, the propriety of combining areas for teaching purposes with the mutual agreement of the authorities concerned might be considered. It is most desirable that all sanitary authorities, especially the larger ones, should give facilities to students to acquire practical knowledge. There has been one conspicuous instance where opportunities were withheld.

In deciding the districts in which the students may be allowed to train for their practical work it is worth considering whether the authorization to undertake the practical training of students for the Department of Public Health should be limited to whole-time medical officers of health. This would obviate the necessity for combining areas, but it would not wholly meet the difficulties experienced.

One further point deserves consideration. Many candidates who present themselves for examination have obviously been handicapped by reason of the fact that they were carrying on other onerous duties during their period of study. The General Medical Council might think it expedient to advise candidates to limit their extraneous duties, during their period of study, to kindred subjects, such as attendances at welfare, venereal diseases, or tuberculosis centres, or at fever hospitals, or to school medical inspection—always provided that these duties are not of so extensive a character as to make undue claims upon their time. Possibly some recommendation of a similar nature in regard to general practice might be advantageous. It is not suggested, however, that the candidate should be barred absolutely from under-

taking any other duties, but a timely warning as to their limitation would be useful.

As an indication of the field over which the practical instruction ought to extend, a draft of the syllabus followed in Liverpool is appended. No doubt it represents fairly closely the course adopted in many of the large teaching centres.

The rules as finally approved will, I am sure, be highly beneficial. The extension to two years of the interval between the attainment of a registrable qualification and the admission to the examination for the diploma is very necessary, and the lengthening of the curriculum will ensure for the candidate reasonable time in which to obtain the necessary knowledge. It will be noted also that under Rule 6 many of the "schemes," though of comparatively recent introduction, are yet highly important and receive due emphasis, while the increase in the population limit is, I think, very wise.

The General Medical Council is to be congratulated upon taking this important step in improving the curriculum for the Diploma in Public Health.

CITY AND UNIVERSITY OF LIVERPOOL.

DEPARTMENT OF PUBLIC HEALTH.

Syllabus of Practical Course in Public Health Administration, etc.

- I. Interviews with Ministry of Health as often as possible.—Forms and methods of official reports; correspondence.
- II. *Housing and Town Planning.*—Housing and town-planning operations.—Lay-out, width of streets, houses per acre, etc.—Artisan and labourers' dwellings.—Cellar dwellings, courts, and alleys.—Unhealthy areas and insanitary property.—Relhousing schemes.—Transport.
- III. *Planning and Inspection of Buildings.*—Building by-laws.—Building construction, materials, foundations, etc.—Better-class houses.—Public buildings, ventilation, etc., of.—Emigration houses, common lodging houses, and sublet houses.—Methods of examination of sanitary arrangements, smoke test, etc.—Ventilation, heating, lighting, water supply.
- IV. *Water Supply, Sources, etc.*—Baths and wash-houses.
- V. *Scavenging and Cleansing.*—Collection and disposal of refuse.—Destructor.—Electric power station.—Utilization of waste products.—Street washing.
- VI. *Sewage Disposal.*—Sewers and drain construction.—Cess-pools.—Sewage farms.
- VII. *Disposal of Dead.*—Mortuaries, cemeteries, crematoria.
- VIII. *Food Supplies.*—General Administration.—Methods of procedure under Public Health Act and orders relating thereto.—Sale of Food and Drugs Acts.—Sampling, etc.; margarine and butter blending factories.—General milk supply.—Cowsheds: registration, control, and regulation.—Abattoir and private slaughterhouses; meat inspection, evidences of unsoundness; wholesale markets.—Preparation of foods; for example, sausage factories, shops, and sale of meat retail.—Fruit and fish markets: construction, arrangement, and inspection.—Importation of foodstuffs; cold storage (see Port Sanitary Department).
- IX. *Industry and Occupation.*—Bakehouses, factory and "underground."—Margarine works, biscuit factories, etc.—Workshops, administration of, etc., under Shop Hour Acts, Employment of Children Act, etc.—Offensive trades, knackers' yards (disposal of unsound meat and of diseased animals).—Stables.—Hide markets, gut scraping, etc.—Suppression of smoke nuisances (boilers, furnaces, steamers, etc.).
- X. *Infectious Diseases.*—Hospitals, planning and administration.—Grafton Street and Fazakerley Hospitals (construction and administration).—Infectious diseases inquiries (sources of infection, contacts, library books, etc.).—House to house inspection.—Disinfection and cleansing of infected houses.—Disinfectors.—Small-pox, measles, whooping-cough, etc., special preventive measures.
- XI. *Veneral Diseases.*—Clinics and hospitals.—Other centres.—Details of scheme as approved by the Ministry of Health.
- XII. *Tuberculosis.*—Special preventive measures.—Colony.—Sanatoriums.—Institutes and dispensaries.—Scheme as approved by the Ministry of Health.—After-care.
- XIII. *Infant and Maternal Welfare.*—Infant welfare centres, day nurseries and hostels.—Ante-natal centres.—Rest homes.—Administration of Midwives Act; stillbirths, ophthalmia wards.—Milk for infants: depots and distributing centres.—Welfare schemes, as approved by the Ministry of Health.
- XIV. *Child Welfare.*—Schools, elementary and industrial: construction, accessory buildings.—Medical inspection of schools and of school children.—System of supervision and after-care school clinics (ringworm, minor ailments, eye, dental, etc.).
- XV. *Port Sanitary Administration.*—General procedure in regard to infectious disease.—Special methods under plague, etc., orders of the Ministry of Health.—Boarding stations and quarantine grounds.—Aliens' Immigration Orders.—Sanitation of vessels.

crews' quarters; emigrants' quarters.—Disinfection of ships; dertization.—Supervision of dock areas.—Cargoes, and disposal of waste.—Importation and storage of foodstuffs.—Canal boats, registration and supervision.—Transport of live animals, cattle boats, trucks, lairages, etc.

XVI. *Executive Duties.*—Sanitary and special inspectors, and of health visitors and female inspectors.

XVII. *Health Enactments and their Application.*—Acts of Parliament and orders made thereunder affecting the public health.—Statutory notices.—Preparation and nature of evidence.—Attendances at law courts, at proceedings, and at inquiries.

XVIII. *Vital Statistics.*—Methods of compiling mortality statistics.—Estimation of population.—Calculation of birth and death rates.—Preparation of Government returns.—Records of infectious cases.—Hospital registers.

XIX. *Special Reports* by students on some of the foregoing.

XX. *Special Visits* to cases of plague, small-pox, or tropical diseases when opportunities arise.

DISCUSSION.

Dr. T. M. LEGGE referred chiefly to Rule 6, and questioned whether the full-time medical officer of health was the best person to give instruction to the pupil, for he was divorced from the general practice of medicine and fulfilled so many other offices that there was danger of his being jack of all trades and master of none.

Dr. HAROLD KERR (M.O.H. Newcastle) expressed his admiration for the excellent and thorough training given at the Scottish universities, but he wondered how it was carried through and how candidates could be induced to take it up. In his experience about half the entrants, after paying the fees and taking the course, did not sit for the examination. The ordeal was hardly worth while, for the public health service offered the poorest financial outlook and very little chance of professional distinction. The new regulations, in his opinion, were overloaded with preliminary technical work, valuable no doubt, but not essential to a medical officer of health. As to Dr. Legge's objection to the full-time medical officer of health as a teacher, he took that as a compliment to his voracity for work, for in the public health service there were no "soft jobs" either in the way of work, worry, or wealth.

Dr. R. J. REECE (Ministry of Health) said that the net effect of the new regulations was to add another year of technical training at school. His experience as an examiner convinced him that the great defect in the majority of candidates was the lack of practical knowledge. He was certain that the new rules would cut down the number of candidates, and very likely those who did take up public health would take it up as a hobby and not as an occupation. As to the remarks of the previous speakers, he reminded them that industrial hygiene did not begin and end in a factory: the whole circumstances of family life must be taken into consideration.

Professor CARSTAIRS DOUGLAS (Glasgow) agreed that a revision of the regulations for the diploma in public health was necessary, and on the whole he was satisfied with it. As a teacher and examiner he felt that though the successful candidates deserved their diplomas, they had very little real knowledge of what public health work meant. In spite of adverse criticism he thought it was right to make an interval of two years between obtaining a registrable qualification in medicine and entering for the final D.P.H. examination. A year or two spent partly in hospital and partly in general practice was an excellent preparation for public health study. As to the training in chemistry, he thought this might with advantage be confined to a sound grounding in the analyses of water, sewage, milk, butter, and similar processes which the medical officer of health might be called upon at any time to perform.

Dr. PICKEN (M.O.H. Cardiff) maintained that public health students should devote the whole of their time to the work, otherwise they could not acquire a thorough knowledge. There was real difficulty in giving practical instruction in administration, for even the whole-time assistant was usually employed in a special branch, and was no better off in this respect than the man engaged in work outside the department. It was, nevertheless, almost absurd to ask men to give up more remunerative branches of the profession and devote their whole time to study so long as the attractions of the public health service were so small.

Lieut. Colonel FREMANTLE, M.P. (Consulting C.M.O. Herts), protested that the D.P.H. course should be on broader, more academic, and truly scientific lines. First, applied physiology should be the basis, not chemistry or bacteriology, which were only useful accessories. Secondly, rural conditions should be considered the basis of healthy living, and everyone should work toward the decentralization of industry. Thirdly, the conception of health and disease in this temperate climate and in this congested country were cramped as compared with tropical and oriental life. Tropical conditions and experience played a large part in the general practice of public health. Fourthly, industrial hygiene must be taught by those experienced in it, but it was absurd for a Ministry of Health and for local health authorities and their officers to be excluded from that most important factor in public health.

Dr. A. K. CHALMERS (M.O.H. Glasgow), President of the Section, in closing the discussion, pleaded for a wide view of public health. It was not the six or eight hours a day spent in a factory that comprised the whole of a man's health circumstances; that was one aspect only, and it gave an imperfect view. He wished particularly to refer to Rule 6, which he considered awkwardly worded. If strictly interpreted, it would be impossible of application, but he understood that the certifying medical officer of health merely had to satisfy himself that adequate instruction had been given, though not by himself personally.

DISCUSSION ON ADMINISTRATIVE REQUIREMENTS OF THE VARIOUS TYPES OF TUBERCULOSIS.

OPENING PAPER

BY

A. S. M. MACGREGOR, O.B.E., M.D., D.P.H.,
Assistant Medical Officer, Public Health Department, Glasgow.

TUBERCULOSIS schemes aim at providing treatment of one kind or another for patients suffering from tuberculosis in its various forms, and are elastic enough to permit of a measure of what is called preventive treatment. The different types of case and the various stages of the disease have their several requirements, administratively described, in the terminology introduced with the National Insurance Act, as sanatorium, hospital, dispensary, or domiciliary treatment. At present these form the main component elements of tuberculosis schemes, the part played by each varying according to local conditions, and the conceptions of those responsible for administering individual policies. Schemes may be said to be complete when every eligible patient is able to obtain appropriate treatment with reasonable promptitude. Judged by this standard few schemes are adequate, and are in general mostly lacking in provision for the advanced consumptive, and for non-pulmonary forms of the disease.

This discussion is concerned, however, not so much with the rôle played by these services as with the various types of patient met with, and the manner in which official schemes, in operation or conceived, may be said to fulfil their requirements. For convenience, we may consider (1) what patients require administrative treatment; (2) the nature of this treatment (including isolation); (3) various accessories to treatment—for example, industrial employment, etc.

1. At the outset we are met by a fairly large class who require diagnosis. Precision in administration depends to a large extent on accurate as well as early recognition of the true nature of the patient's illness. It is necessary to say, though it may seem an obvious and trite remark, that, before qualifying for treatment, a patient should be suffering from tuberculosis. There is no doubt that many errors in diagnosis are made, partly because discrimination between tuberculosis of the lung and other affections which simulate it is often a matter of considerable difficulty, but partly also because of bias towards his particular specialty by the tuberculosis physician. The function of a tuberculosis dispensary should be as much to prevent erroneous diagnosis as to secure the early recognition of tuberculosis. A good many patients are treated as tuberculous owing to misreading of the symptoms manifested and of the physical signs detected. The medical

officer responsible for routine diagnosis should therefore be a competent physician and should have at his command adequate facilities for differential diagnosis, among which x-rays have a very important place. Radiographs are extremely valuable, if studied in conjunction with the clinical evidence, and have an educative value in checking over-refinements in diagnosis, unless, of course, they are subjected to bizarre interpretations. In most doubtful or suspected cases observation at the dispensary will usually suffice, although there is a considerable group which require observation in a hospital ward before the true nature of the case is disclosed. Stress is laid upon this aspect of administration because recent experience has shown the importance of placing diagnosis and facilities for it in the forefront of a tuberculosis scheme. In a great industrial city like Glasgow there is a very large amount of chronic respiratory affection both in children and adults, sequels of successive waves of measles, whooping-cough, and bronchiopneumonia, while the latter are particularly prone to chronic bronchitis and its complications. For another thing, one must bear in mind the grave consequences, material and mental, which often follow a diagnosis of tuberculosis. As an illustration of these remarks I may mention the following data from the experience of the past eighteen months at one of the tuberculosis dispensaries. Out of 109 cases sent for diagnosis to the dispensary by medical men in the neighbourhood, 20 were suffering from tuberculosis; the remaining 89 were variously diagnosed as follows—chronic bronchitis 63 cases, cardiac disease 9 cases, bronchiectasis 4 cases, the others being variously classified as pneumonia, no disability, silicosis, aneurysm, empyema, and gunshot wound of chest with fibrosis.

A brief reference may be made to another clinical group (where administration is rather helpless)—that is, those whose disease has made considerable progress before it is recognized. This class of case has not much lessened in number among the civilian population since tuberculosis schemes came into being. Unless the disease is introduced by a haemoptysis, or unless it is detected in a contact, the tendency is for the sporadic case to be recognized late rather than early, and by that time mischief to other members of the family has very often already been done.

Administration has also a duty, difficult to define, towards contacts in general. Apart from those who have definitely sickened, whether the infection which they may be presumed to have received will result in immunity or not there is no means of knowing. We can at least endeavour to maintain their general health in whatever way may seem best. In France, for instance, under what is known as the Grancher system, the children of consumptive parents are boarded out in the country. This procedure recognizes the fact that between reception of infection and sickening there may intervene a period of many years, the finally declared focus in the lung being the termination of a long process, the story of which is difficult to read. It was thought at one time that preventive treatment could be applied during this intervening period to certain selected clinical types with some degree of precision. Hence arose the effort to detect that very vague entity, the pretuberculous child, but it did not meet with much success. Short of the radical procedure of the Grancher scheme, the danger of massive infection may be reduced when the infective patient is taught to observe the rules of prevention, or, better still, when he is removed to an institution especially from a small overcrowded house.

2. We now come to the administrative requirements of the various types of the definite case. Institutional treatment here takes the form of the sanatorium or hospital. Generally speaking, the early case or case with good resistance goes to the former; and the advanced or hopeless case to the latter. Between these two types, however, there exist numerous clinical varieties of patient belonging to a vague generic group known as the "middle" or "ambulant chronic" type, composed of patients whose disease progresses slowly or fitfully, with intervening periods of quiescence, during which they are fit for moderately light tasks. This is a difficult group from an administrative point of view.

The various aspects of the declared case can best be discussed by reference to a concrete study of a definite section of a city population. Some time ago an analysis was made by Dr. J. A. Wilson and myself of the considerable group of ex-service men

then in the city who were suffering from pulmonary tuberculosis, with special reference to their clinical condition and degree of disablement at the time. It is difficult to give an even approximate idea of the great variety of clinical types, but the following broad grouping may serve as a basis for discussion. There were in the city 785 ex-service men who had been notified as suffering from tuberculosis of the lung. Among these were 122 (15 per cent.) who could not be regarded as definite cases. Their disability was due partly to other lung affections, or to other than lung affections. The remaining 663 patients, accepted as definite cases, were in a variety of stages of the disease, as follows:

		Tubercle Classification:			
		I.	II.	III.	Totals.
Arrested	38	11	—	49
Quiescent	98	175	52	325
Active	36	133	120	289
Totals	172	319	172	663

The "arrested" group contains those who had been free from symptoms of toxæmia for over eighteen months, and the "active" group those who showed recent or present signs of activity. The "quiescent" or stationary group, composing one half of the total, is in the majority, while as regards extent of disease, a similar proportion falls into Stage II. An average adult male population would probably sort themselves out in much the same way, though there might be among them a higher proportion of advanced types. The chronic moderately advanced case is therefore the preponderating clinical type. A good many, probably the majority, of those in this group are fairly fit and able to do a fair day's work, their disability being proportional to the extent of the fibrotic change in the lung. Many of them have ceased to excrete bacilli in the sputum, or do so intermittently; they are constant attendants at the dispensaries in winter and infrequently during the summer months, when their symptoms become greatly alleviated or almost disappear.

But this is not the whole story as regards disablement. In a considerable proportion of cases the tuberculous affection of the lung is not the sole handicap. Where the major disease is active and advancing the presence of a complication may be a subsidiary element in the case, but it often happens that a mild and retrogressive tuberculous affection is overshadowed by the presence of a concurrent disability. This is particularly so where chronic bronchitis and tuberculosis coexist. In the above series of 663 cases the principal concurrent disabilities, excluding minor affections and including only those which gave rise to definite physical handicap, were: chronic bronchitis 104, other tuberculous lesions 11, other affections 15, heart disease and aneurysm 8, poor physique and deformity of chest 15, recurring pleurisy 8. Many with chronic bronchitis are quite markedly disabled; the tuberculous element is retrogressive; they appear to excrete bacilli often at odd intervals; if admitted freely to institutions they tend to silt up the accommodation; they are susceptible of scant improvement; and were it not for the fact that they are commonly homeless or indifferently housed, they would have little claim on administrative attention.

On the institutional side, tuberculosis schemes meet the requirements of these various groups by the provision of sanatoriums and hospitals either as separate or combined institutions. There is no doubt about the necessity for institutional provision for the advanced infectious case. The extent of this will, of course, vary with local conditions, and especially with housing conditions. Hospitalization of this type of case has always been one of the main objectives of the Glasgow scheme, principally because so large a proportion of the population live in small houses (13 per cent. in one apartment, 49 per cent. in two apartments, 21 per cent. in three apartments). Hospital, as apart from sanatorium, beds for tuberculosis of the lung in Glasgow have now reached the approximate number of 520 under the local authority, and 250 in Poor Law institutions by arrangement with the local authority. Apart from the public health value of this procedure, it is a much-appreciated humanitarian policy. It will be observed that the large chronic ambulant group

described above receive such institutional treatment as they require in hospitals, and are often "in and out" several times during their long career. Whether this is the best way of meeting their requirements will be discussed presently.

3. Various schemes have more recently been proposed for amplifying administrative measures in the direction of training the consumptive in a suitable occupation, with which to re-enter employment, or actually providing him with a definite occupation suited to his physical condition; the form of the hygienic workshop or the village settlement.

We may now consider the various types of case to whom these proposals might apply. In regard to industrial training as an avenue to re-entry into employment, careful selection of candidates is essential. It will be convenient to discuss this with reference to the material comprising the group of 785 notified cases referred to above, taking them as an average sample of a male industrial population from whom candidates might be drawn. Of these, some 122 cases, not regarded as definitely suffering from tuberculosis, would first be discarded. Eliminating next those who are frankly disabled by advanced disease or reduced to low working capacity by other infirmities, a group of 230 patients would fall out of consideration. Apart from physical fitness, however, a man's suitability for training depends also on his character and temperament. For the purpose of training in a new occupation, in which a candidate has to make good in the future, a scheme should be such as to attract the best type of patient. From this point of view we were led to compile a group of some 191 cases who, from our knowledge of them, and apart from questions of physical fitness, would be unlikely to be suitable for a scheme requiring initiative and co-operation on the part of those participating in it. Some were quite frankly unsuitable, while others who seemed to have suffered loss or enfeeblement of the will power as a result of their disease would scarcely be fitting candidates, unless the psychological aspect of the disease was dealt with at the same time.

After eliminating these groups, there remain 242 patients, out of whom on careful scrutiny we might select 127 as representing the best possible types, both physically and temperamentally, composed of 18 "probably arrested" cases, 75 quiescent cases, and 34 with some activity still present. Looking at the members of this group more closely, it is necessary to consider the nature of their present occupation, the conditions under which it is carried on, and also the fitness of each to continue at his particular trade. All but twenty of these men were employed in skilled or semi-skilled occupations, many of which were not at all unhealthy. In the case of others, continuance at a particular trade would depend not so much on its nature as on the conditions under which it is carried on, so that the question becomes rather one of re-employment under more favourable conditions than one of training in a new occupation. In a few the trade itself was frankly unsuitable. All these considerations make the question of selection for retraining a somewhat complicated one. An important aspect of the question is the point of view of the men to be trained. The workman, in this part of the country at any rate, is shrewd enough to show concern as to his future prospects in the proposed new sphere of employment, and is averse to retraining without some assurance on this point. For these reasons training for the purpose of re-entry into employment would appear to be limited in its scope and might not attract the best types of workmen, unless associated with a scheme of "placing" the trainee later on. This is one of the points emphasized by Dr. Noel Bardswell in a recent report, in which he states that with the exception of twelve men settled at or by the institutions to which they had been sent for training, none of the 160 London men who had passed through training centres during 1918-21 were now employed at the occupation in which they received their training.

On the other hand, the village settlement would meet many of these points. It implies permanent employment under sheltered and hygienic circumstances, associated with housing conditions for the patient and his family beyond reproach. It would, further, by permitting adaptation of the character and amount of work to the physical fitness of the worker, allow of a fairly wide selection of candidates from among the various types of case, including many of the "chronic ambulant" group. Social suitability would then become the principal factor in selection. This scheme is subject to

the broad criticism that, apart from the difficulties in administration and organization which would attend its adoption on a large scale, it would secure for the consumptive and his family every possible hygienic and economic advantage, quite beyond what could be attained by the majority of the population. On the financial side the initial cost would certainly be high. As regards running cost, the claim has been made—and it is possible that experience might show—that the combined expenditure now incurred in respect of invalidity due to tuberculosis in adult males suitable for such a scheme by the local authority, the Poor Law authority (in respect of the maintenance of dependants), and under the Insurance Act, might be little less than that of a measure of this kind, taking into account on the credit side the revenue which would accrue from the labour of the settlement. These points could only be tested by actual experiment. However admirable schemes of this kind would be for the individual, sufficient is not yet known about the natural history of tuberculosis to make it certain that, as a public health investment, they would justify their cost.

Reverting to the large ambulant chronic group described above, composed of men with more or less extensive disease, very often with other infirmities, and with a working capacity that varies with the season, we have seen that the only form of treatment provided is the hospital, which is commonly an annexe of a fever hospital where lack of interest and occupation tends to create a feeling of boredom and pessimism. If the problem of administration were simply the provision of employment, this could be accomplished by the hygienic workshop, whose scope and aims are well known. It is, however, impossible to deal administratively with this group without reference to their housing conditions, and the hygienic workshop would require to be associated with some simple residential accommodation for those who are indifferently housed. As a solution of the problem, this would be less expensive, though less ideal, than the creation of village settlements.

In the face of so many different aspects of the disease, with varying requirements, administration finds it difficult to choose definite lines of action. For an affection like tuberculosis, which is complex in its causes, there is no simple and straightforward policy. Administration tends to be cautious and to look for definite preventive and public health sanctions when confronted with new schemes of uncertain dimensions and cost, and to regard new policies in their widest possible application before allowing them to assume undue preponderance over other aspects of public health policy, among which improvement in the general health and in the conditions of life and work of the population generally take a prominent place.

In conclusion, reference may be made to the claim to treatment of the non-pulmonary forms of tuberculosis. Institutional facilities for this group are very inadequate, and the large number of advanced surgical affections met with will not diminish until there is sufficient and appropriate accommodation for treating them in their early stages.

DISCUSSION.

Dr. MARCUS PATERSON (Frimley Sanatorium) complimented Dr. Macgregor upon the clearness with which he had explained the present situation. There was one point upon which he (the speaker) claimed to have exceptional experience, and that was the hospitalization of the advanced case. The two difficulties which troubled him most were the local health authority, with their officers, and public opinion. Voluntary segregation was comparatively easy for the "good" patient, but the majority became impatient of the restraint of an institution. If, by way of reward for good behaviour, or of recompense to restraint, he allowed a patient to return home for a short time, the M.O.H. and his subordinates were up in arms against him for re-infecting the premises which they had so carefully disinfected. It was unfortunate that every patient in an institution had to be tectotal: if only public opinion would allow a wet canteen hospital administration would be an easy matter. Hygienic conditions and good food converted many of the very bad cases into freely ambulant cases. If these had had some special treatment—for instance, a new serum—the serum would get the credit, not the wholesome régime.

Professor CUMMINS (Cardiff) said that Dr. Macgregor, in calling attention to the large group of ambulant chronic cases, had put his finger upon the outstanding problem of all tuberculosis schemes. These cases were too advanced for sanatoriums and too well for constant residence in hospital. They were the most dangerous of all, for they invariably came from poor homes and were the source of repeated and formidable infection to younger members of the family. He attributed the high tuberculosis death rate amongst children under 4 years of age in large towns to the presence of these cases. He considered the village settlement the ideal scheme provided the necessary financial provision could be made and patients persuaded to go there. These were the objections raised by every member of the medical staff—all of them experienced tuberculosis officers—to the scheme which he had recently propounded to the Welsh National Memorial Association. Hope, he said, would entice the early case to the sanatorium, and despair would drive the late case to the hospital, but nothing short of compulsion would bring the chronic ambulant case into the clasp of efficiency of the village settlement. There were depressing facts to be discovered in all tuberculosis schemes, but there was no reason to lose heart. Both the public and the medical profession generally were beginning to take a more intelligent interest in the work. Earlier diagnosis, better accommodation for patients, better conditions of housing, pay, and food, contributed to bring some measure of success to the efforts to combat tuberculosis.

Dr. PREST (Ayrshire Sanatorium) pleaded for concentration on the early case. It was too late to wait for the discovery of tubercle bacilli in the sputum or x-ray demonstration of lesions in the lungs. Definite diagnosis should be made at an earlier stage by consideration of the symptoms of toxæmia. He himself placed great reliance on the rectal temperature, which was the only reliable way of taking the temperature. Unfortunately, as Dr. Macgregor had found out in Glasgow, it was extremely difficult to provide accommodation for early cases, on account of the large number of chronic ones.

Dr. CROCKETT (Bridge of Weir Sanatorium) agreed as to the importance of getting the cases early. Tuberculosis was very difficult to diagnose in its initial stages. There should be observation houses where doubtful cases could be thoroughly gone into and decided upon. Length of treatment was most important; two or three months was seldom of any service. Considerable liberty should be given to patients under treatment as an inducement to continue, but he did not believe in "week ends," as that tended to unsettle the patient.

Dr. HALLIDAY SUTHERLAND (Ministry of Pensions) repeated the dictum of Emile Sergent of Paris to the effect that no clinician, however experienced, could make a firm diagnosis of early tuberculosis by means of percussion and auscultation alone. X rays, which should be installed in all tuberculosis dispensaries, the subcutaneous tuberculin test, repeated examination of sputum, should all be employed, and he would add a fourth, the complement fixation test. Public health authorities should wait for the results of the gigantic experiment now being performed by the Ministry of Pensions. Through that body adequate treatment and financial assistance were being provided for all cases. If it failed nothing short of the abolition of slums and poverty would be likely to succeed.

Dr. T. M. LEGGE (Home Office) suggested a wider extension of medical supervision in the factories and workshops to detect the early cases and to keep them under supervision with regard to the physical condition of the workman, the nature of his work and the conditions under which he worked. At present, under the National Health Insurance Act, the workers streamed to the panel doctors when they became ill, but there was no return stream from the doctors into the factory to detect and remedy the illness which must ultimately fall upon the Insurance Fund.

Dr. W. H. DICKINSON (Tuberculosis Officer, Newcastle-upon-Tyne) also insisted upon early diagnosis being placed in the forefront, which meant adequate staffs and proper facilities, especially x rays. The administration of domiciliary treatment required improvement. Over 80 per cent. of the treatment under sanatorium benefit was given in the home. Examination of contacts should be made an essential part

of every scheme, and he suggested the granting of assistance being made conditional upon the performance of this part of the work, especially in cases where there was a death from tuberculosis in the home.

Dr. C. W. CUNNINGTON (Hampstead) said he, as a general practitioner, spoke with some diffidence amongst so many experts, but he was impressed with the importance of the food factor. As the price of food went up so the tuberculosis death rate rose after it, and declined similarly. In his humble opinion the checking of tuberculosis had more to do with good feeding than all the administrative action that had been taken.

Dr. A. K. CHALMERS (M.O.H. Glasgow), President of the Section, said he also was impressed by the influence of improved food supply. It was much more important than the factor of heredity, for only one in three cases had a hereditary history. He also called attention to the anomaly of providing a pension for the tuberculous soldier, but none for the similarly afflicted civilian. Human sentiment was against sending a person into an institution to die; that was the difficulty in dealing with the advanced case. The general impression he had obtained from the discussion was that they had now, in the matter of treatment, come to a fork in the road.

Dr. MACGREGOR, in reply, said that the majority of the speakers had simply stroked the "t's" and dotted the "i's" of the present-day schemes. Nobody could say what the next step ought to be. He agreed with Dr. Halliday Sutherland that we should wait and see what results came from the Ministry of Pensions' efforts, but he was quite convinced that segregation of the advanced cases was essential.

SECTION OF INDUSTRIAL DISEASES AND FORENSIC MEDICINE.

JOHN GLAISTER, M.D., F.R.F.P.S. Glasg., D.P.H. Camb., F.R.S.E., President.

THE IMPORTANCE OF TEACHING MEDICAL JURISPRUDENCE TO STUDENTS OF MEDICINE AND LAW.

BY

ANDREW ALLISON, M.B., Ch.B., B.Sc., D.P.H.,

F.R.F.P.S. GLASG.

Professor of Medical Jurisprudence and Public Health, St. Mungo's College, Glasgow.

MEDICAL jurisprudence has been defined as the application of medical knowledge to the purposes of law. It is a compulsory subject of the medical curriculum, but the scope of the teaching and the extent of the examination vary considerably. With some examining bodies the questions on medical jurisprudence form only part of a paper which is devoted to the combined subjects of medical jurisprudence and public health. In other cases separate papers are set for each subject. Entrance to the legal profession is possible without a knowledge of forensic medicine. The subject is not compulsory for those seeking to become solicitors or reading for the English Bar, but it is a compulsory subject of examination before admission to the Faculty of Advocates in Scotland.

While medicine, surgery, midwifery, and the other subjects of medical study all lend their aid to the medical jurist, scarcely any of the standard textbooks refer to points of medico-legal interest, and the practitioner who has given no consideration to medico-legal problems will find his position as a witness far from satisfactory. The physician and surgeon are concerned with the healing of the sick, but the medical jurist must view disease, accident, and death from a different standpoint and be prepared to assist the law in arriving at a just decision. The questions which have to be answered in the witness-box are often such as have received no attention during clinical practice, and no practising member of the medical profession is exempt from being called as a witness in any of the numerous cases, civil and criminal, in which medical evidence is indispensable.

To the lawyer engaged on a case involving medical questions the advantage of a knowledge of medical jurisprudence is obvious,

as he can hardly be expected to understand medical science by intuition. Much useless controversy would be avoided if the lawyer and the doctor had each some knowledge of the subject and function of the other.

It is interesting to note that discussion of medico-legal questions is not common in the various professional societies. The Medico-Legal Society, which holds its meetings in London, is the only one which devotes itself entirely to such topics. Scotland, with its different laws and legal procedure, has no such society.

The importance to the medical practitioner of a knowledge of the statutes which affect him in the practice of his profession is too evident to require discussion. Questions of registration, professional privilege, and professional secrecy, the functions of the General Medical Council, the obligations imposed regarding death certification, and similar matters are essential subjects in any course of medical jurisprudence.

Clear thinking is essential for both lawyer and doctor, and is impossible on medico-legal subjects unless these have been studied and their legal and medical aspects understood. While the doctor should understand the precision that is required by law, it is equally important that the lawyer should appreciate the limitations of medical evidence. Failure to recognize these principles is one of the reasons why medical evidence is sometimes regarded as unsatisfactory.

It is often extremely important to fix the time at which a person died and thereby associate an accused person with the commission of a murder. To do this with accuracy is beyond the power of science, yet how often does one find the medical witness pressed to state that death must have taken place at least a given number of hours before the time of his examination. Suppose he says twenty-four hours: a well-informed cross-examiner would certainly want to know what difference there would have been in the signs if the person had only been dead for twenty-two hours. It is, however, within the ability of the medical examiner to state that the signs found on a body are under the circumstances consistent with death having taken place within a specified period. That is all the help medical science can afford and the only opinion the court has a right to expect.

It is not uncommon for counsel, particularly defending counsel, to ask a general question and to utilize a favourable answer in his pleading. The results obtained from an average can never be applied to a particular case, and this line of examination defeats the object of medical evidence, which is to place before the court, regarding a technical matter, the truth, the whole truth, and nothing but the truth.

Sexual offences afford excellent examples of the need for minute observation, accuracy in describing the conditions found, and clear thinking in arriving at conclusions. In such cases the punishment meted out to the guilty can scarcely be too severe, but from the nature of the case the jury are often biased against the prisoner, and loose medical evidence may help to cause a miscarriage of justice. During the course of a trial for rape a medical witness stated that the hymen had been ruptured and that complete connexion had taken place. Neither the examination-in-chief nor the cross-examination elicited any information regarding the presence of a fresh tear; nor was the question of blood about the parts discussed, and this in spite of the fact that the girl was aged about 10 and her alleged assailant of adult age. In another case the witness thought the girl had been tampered with because the entrance to the vagina was somewhat lax. Truly a laxness of description hard to beat. In charges of rape undue importance is often given to the presence of seminal stains on the clothing of the accused. The possibility of their having been produced during legitimate sexual intercourse should always be placed clearly before the jury. In cases of alleged indecent assault on young girls marks of violence are, in the experience of the writer, only occasionally found. This can be accounted for by the nature of the interference, and the absence of positive medical evidence does not mean that the child has not been subjected to indecent practices. Clinical evidence of venereal disease should always be confirmed by bacteriological tests. In these cases consideration should also be given to the factor of time—namely, the period which has elapsed between the alleged assault and the onset of symptoms. The presence of similar disease in the accused does not prove that he communicated it but merely that he was capable of doing so.

Cases involving compensation for injury bring doctor and

lawyer into contact more frequently than any other type of case, and it is here, even more than in criminal work, that the lawyer tends to regard the medical expert of the opposite side as a hired partisan. Too much has probably been made of the differences of opinion of medical men in these cases. It must be granted that doctors may honestly differ, also that even well-informed doctors may make mistakes; lawyers do both. Fashion at present tends to regard all claimants for damages as malingerers, or at least guilty of exaggerating their symptoms, and accuses the medical witnesses, particularly the much maligned general practitioner, of bolstering up a questionable case. It is doubtful if the evidence for the insurance company can justly be claimed to be less partisan than that for the claimant. Such accusations of bias are difficult to substantiate, and are probably no better founded than the popular belief that insurance companies are always eager to make a settlement favourable to themselves but unjust to the injured. The reports presented by the different medical witnesses are often substantially the same and the alleged difference of opinion only becomes acute on cross-examination, as the lawyers emphasize the points favourable to their respective clients. The meaning of the phrase "fit for work" is a common stumbling-block. When the pursuer pleads that he is unfit for a particular occupation it is not unusual for the employer to bring forward as a witness a workman suffering from a similar disability and employed on the work in question—cynics would say for the work in question. Viewed scientifically this line of evidence does not carry conviction and is not infrequently an attempt to compare things which are unequal and therefore cannot be compared. Valuable evidence bearing on the average capacity for work would be got if the employers brought forward statistics showing, for each class of injury, the nature of the employment before and after the accident.

That the legal mind is often more impressed by the claim which a client has than by the nature of his injuries is well illustrated by the following case. A wooden shutter fell and struck a man while he was walking along a public street. I examined him in the police office within half an hour of the accident and found no signs of physical injury and no evidence of shock. He ceased work, and many months afterwards his case came up for trial in the Court of Session. The evidence of his own medical attendant was unfavourable to him, but a hospital physician who had seen him once testified that he was suffering from arterio-sclerosis which might have been aggravated by the accident. It was not disputed that the pursuer had been struck by the shutter, and a remark by the judge, that as liability had been admitted he could not understand why the case had been brought to trial instead of being settled out of court, apparently determined counsel for the defence not to call witnesses. It is clear that there was here no real medical proof of disability resulting from the accident. An interesting feature of the case is that I had been asked by the agent for the pursuer to give evidence for his client and had refused on the ground that I could say nothing which would be helpful to him. Our conversation ended by his remarking, "Well, he at least suffers from neurasthenia." The court awarded his neurasthenic client £200 and expenses.

Instead of allowing a man's disability to be determined by a forensic duel the assessment of injury and incapacity might, with advantage, be referred to a medical referee or board of referees having no connexion with either side, the court stating the questions to which answers were required. The provision of medical referees under the Workmen's Compensation Acts is an admission of the fact that the assessing of disability is a medical matter. It is not the fault of the medical profession that only a small proportion of cases are referred to these officials.

The criminal responsibility of the alleged insane has given rise to sharp conflict of opinion between law and medicine. The difference is due largely to failure to recognize the standpoint of the other side. A criminal act implies the existence of intention, will, and malice, and involves punishment. But if the accused is proved to have been insane at the time he committed the act he is either sent to an asylum or handed over to the care of his friends, depending on the nature of the offence. The difficulty lies in determining what constitutes insanity. According to the law of England "to establish a defence on the ground of insanity it must be clearly proved that at the time of committing the act the accused was labouring under such a defect of reason from disease of the mind as not to know the

nature and quality of the act he was doing, or, if he did know it, that he did not know that what he was doing was wrong." To the jury is left the task of deciding. This legal test of insanity arose out of the McNaughton case and is based on answers given by fourteen judges in 1843 to certain questions put to them by the House of Lords.

The idiot and the maniac may satisfy the legal test, but certainly not the majority of the certified insane. Medical men recognize that there is no infallible symptom or character which will distinguish the criminal of unsound mind from the sane criminal. It has been truly said that "the mad and the bad pass by insensible gradations the one into the other."

Not all judges have found the McNaughton decision acceptable. With regard to the man Ware, who murdered a fellow patient in an asylum, Mr. Justice Hawkins remarked:

"It would be impossible to say that Ware did not know that he had killed a man, because he said himself that he had, and it would be impossible for anyone to urge that he did not know it was wrong, for he wanted a promise that he should not be punished, but unless one put a totally different construction on the law that would have to be proved, although no man in his senses would suppose that any jury would find Ware responsible for what he had done."

The late Lord Chief Justice Cockburn expressed himself as follows:

"I have always been strongly of opinion that, as the pathology of insanity abundantly establishes, there are forms of mental disease in which, though the patient is quite aware he is about to do wrong, the will becomes overpowered by the force of irresistible impulse; the power of self-control, when destroyed or suspended by mental disease, becomes, I think, an essential element of responsibility."

In Scotland, as long ago as 1863, Lord Justice Clerk Inglis told the jury that if they were satisfied that a person charged with murder, as was the prisoner, was the victim of insane delusions at the time of commission they had no need to inquire whether he knew what was right from what was wrong or whether he knew what was murder in the eyes of the law, or what was a punishable act. The state of the law is clearly unsatisfactory. The jury are swayed by many considerations and no one can tell what their verdict may be in a particular case. There is always the danger that the merely vicious may escape punishment while the mentally unsound may be sent to imprisonment or even to the scaffold. Mere recriminations will not cause the difficulties to disappear, and it is the duty of the medical and legal professions to assist each other in reaching a satisfactory conclusion. The fact that the plea of insanity usually succeeds where epilepsy can be proved shows the appeal that is made to both legal and lay minds where something is brought forward which can be easily apprehended and appears to indicate that the interpretation of the term "insanity" will become more liberal as the nature of unsoundness of mind becomes better understood.

It is a presumption of law that a medical man can answer any question of a medical nature. A coroner may call on the nearest practitioner to make a *post-mortem* examination, though such practitioner may be far from familiar with pathological changes and may not even have been present at a *post-mortem* examination since his student days. Or a doctor may be required to give evidence regarding the only case of homicidal wounding he has met with during many years of practice. The opportunities available of becoming acquainted with the practical aspects of forensic medicine are therefore of considerable importance. Lectures must be largely relied upon but should be illustrated by photographs, lantern slides, microscopic preparations, museum specimens, and demonstrations of the methods of testing blood and seminal stains. Sometimes a small amount of practical toxicology is included, but it is doubtful if it is worth while teaching the analytical side of the subject, as the time available is not sufficient to make the teaching of practical value. The symptoms, treatment, and *post-mortem* appearances of the commoner poisons should be taught, and also the method of making a *post-mortem* examination in a case of suspected poisoning. It would be an advantage if some definite provision were made for clinical teaching in connexion with cases of poisoning. These cases when admitted to hospital may pass to any of the medical wards and thus the study of poisoning in the living is to a large extent lost as the students are scattered throughout the various clinics. Where a medical school is attached to a hospital it would be an advantage if all such cases were admitted to the same ward and if the lecturer on medical jurisprudence was given the privilege of demonstrating them to his class.

The chief clinical material of the medical jurist is the dead body, but the utilization of this for teaching purposes is beset with difficulties, and safeguards are necessary before a class of students can be introduced to a necropsy made for legal purposes. Nevertheless, all will agree that the student should be brought into contact with realities as much as possible. More frequent *post-mortem* examinations are greatly to be desired. Where there is any likelihood of a criminal charge being made a dissection of the body is always carried out, but this is not done in many cases of accident, suicide, and sudden death. The great majority of cases of poisoning in this country are accidental or suicidal, and if few *post-mortem* examinations are made, where do the authorities expect to find their experts when the occasional case of homicidal poisoning arises? There are many cases of sudden death where the probable cause is apparent after ordinary inquiry and where a necropsy is unnecessary. In those where there is doubt regarding the underlying pathological cause a *post-mortem* examination should always be made. Had one been made on Chapman's first victim antimony poisoning would probably have been discovered, and there would have been no subsequent victims. In cases of accident the apparent cause of death is not always the real cause, which can only be definitely discovered after dissection.

Unless a *post-mortem* examination has been made the verdict "Found drowned" is unjustified and consigns a body to the grave with the true cause of death undetermined. The excessive infantile mortality among illegitimate children as compared with those born in wedlock indicates the need for more thorough investigation. Owing to the difficulty of proving criminal neglect very few prosecutions would be likely to result, but the information of the true causes of death would be of the greatest value. With more frequent *post-mortem* examinations, cases of accident, suicide, and others not likely to involve criminal proceedings could be used for teaching purposes and medical evidence would be correspondingly improved.

The creation of a Central Institute of Medical Jurisprudence has sometimes been advocated. Such an institution would be useful in providing for the investigation of matters of special importance and for the training of a body of men specially skilled in the problems of legal medicine, but the necessity for teaching medical jurisprudence to students of medicine and law would still remain.

DISCUSSION.

Sir W. H. WILLCOX considered that the teaching of forensic medicine in the medical schools and universities at the present day required serious attention. The amount of time and thought which the medical student paid to forensic medicine was largely determined by the examination test which he must satisfy before qualification. There could be no question but that there had been a great deterioration in the requirements of the examining boards in the subject during the past fifteen or twenty years, and a corresponding diminution in the time and attention which the medical student devoted to it. For example, at the University of London there was formerly a separate paper on the subject of forensic medicine, a practical examination of two hours in the laboratory, and an oral examination. About fifteen years ago the examination was entirely altered and replaced by a joint paper in forensic medicine and public health, with a joint oral examination, the practical examination being abolished. Reduction in the scope of the subject led to deficient study of the subject to be feared that in many of the medical schools the candidate's knowledge of forensic medicine had become more or less of a formality. The inevitable result had been that too often medical students had become qualified with a knowledge of forensic medicine quite inadequate for the practical application of the subject when called upon to give evidence in a case or assist in a medico-legal investigation. There were many indications that the legal profession was beginning to realize the increasing importance of the subject in the legal curriculum and to the practising lawyer. Dr. Spilsbury had recently given to the legal profession a course of lectures on forensic medicine of which high appreciation had been expressed at the discussion at the Medico-Legal Society. He considered it most important that the practice of forensic medicine should be centralized more than it had been. In England little centralization existed, but in Scotland medico-legal work was more centralized. Centralization would ensure the

pathological investigations being carried out by experts. It would lead to more accurate work, would promote and facilitate research and the more extensive publication of new observations. It could not be too strongly insisted upon that *post-mortem* examinations should wherever possible be made by pathological experts who were constantly engaged in the work.

Mr. J. DRUMMOND STRATHERN (Procurator-Fiscal, County of Lanarkshire) took part in the discussion, on the invitation of the Section. He said that it was important that the medical practitioner should have a clear appreciation of what the law required of him in the ordinary walks of his professional vocation. The conditions found on the most casual or incidental examination might prove of very great consequence in determining a question which might subsequently arise. It was no doubt true that lawyers were inclined to expect too exact knowledge from medical witnesses, and it might be that lawyers failed to appreciate the limitations of medical science. On the other hand, it frequently happened that medical men were most unsatisfactory as witnesses, by reason of the fact that they did not appreciate the importance of a point, even when it depended for its statement on the result of their own observations. Two or more medical witnesses examining the same condition at or about the same time frequently differed materially on the facts; but in the realm of opinion based upon the same observed facts, opinions frequently differed widely, especially so when pressed under expert cross-examination. He accordingly thought that, in so far as medical jurisprudence was taught to medical students, there should be included in it some at least of the elementary principles of law, particularly those of evidence. Where a malingerer recovered compensation, in nine cases out of ten his case was supported by medical opinion which was apparently reliable, and if lawyers did err their blunder consisted merely in this, that they accepted the considered opinion of the wrong set of medical witnesses. Questions of insanity were questions of fact *plus* medical opinion. It could not be suggested that medical opinion on this matter had not varied from time to time, and in these days it was very difficult to obtain clear evidence on many cases of alleged insanity. Dr. Allison had suggested referring the assessing of disability to a medical referee or board of referees. That, in his (Mr. Strathern's) view, should not be encouraged, as it was inconsistent with the spirit of our law. There was great justification for the extension of the practice of having medical assessors when questions of that kind were under consideration. The fact that very few cases under the Workmen's Compensation Acts were referred to medical referees was the best evidence that such procedure did not command public confidence to the same degree as a court.

Dr. GODFREY CARTER emphasized the importance of more consideration being given to the study of forensic medicine by all medical graduates. He advocated that in all large cities the posts of divisional surgeons to the police should be abolished and the duties placed in the hands of one man. This official would devote most of his time to that work, and the appointment should carry with it the lectureship in forensic medicine where that post existed. He urged that students should be given permission to witness *post-mortem* examinations made at the public mortuary in cases presenting a possible medico-legal aspect, unless secrecy was necessary, and that these students should afterwards attend the local courts to hear the evidence and particularly to study the giving of medical testimony.

Sir THOMAS OLIVER said he was glad to learn from Professor Carter that arrangements were now being made in Sheffield whereby cases coming under the head of medical jurisprudence were to be dealt with by the professor of that subject in the university. This had been the case in Scotland for many years, for between the Crown and the university professors of forensic medicine there had always been, in criminal matters, the closest connexion. Sir William Willcox had stated that his colleague, Dr. Spilsbury, had in London given lectures on some of the medical aspects of forensic medicine with great acceptance to lawyers. He himself would like to see similar sets of lectures on the legal aspect of forensic medicine to medical men. There was only one other point to which he would refer—namely, Dr. Allison's allusion in his remarks under the Workmen's Compensation Acts to men partially recovered, "fit for work." The question of "light work" was always a difficulty, for if men who were

partially recovered were allowed to do light work the trade unions interfered and prevented these men doing light work and receiving money from compensation or other sources.

Dr. ALLISON, in reply, emphasized the fact that in cases under the Workmen's Compensation Acts he did not advise that the function of the court should be entirely abolished, but merely that the medical aspect of the case, the assessing of the degree of a man's disability, should be left to a medical referee or board of referees independent of both plaintiff and defendant. This mode of assessing disability was practised with regard to those who had served during the war, and appeared to meet with general acceptance. He also thought that the small number of cases referred to medical referees was not to be accounted for by any want of confidence in the fairness of these officials, but by the fact that both sides had to agree to the reference. Lawyers had frequently admitted that when the "other side" desired a reference to a medical referee they invariably opposed it because they knew that their opponents' case must be good, and they preferred to take their chance in open court.

DANGERS TO HEALTH ARISING FROM THE USE OF INDUSTRIAL PREPARATIONS OF ARSENIC.

By Sir W. H. WILLCOX, K.C.I.E., C.B., C.M.G., M.D.,
F.R.C.P.,

Physician to St. Mary's Hospital, London; Medical Adviser to the
Home Office.

INDUSTRIAL preparations of arsenic are largely used at the present time, and numerous instances of poisoning by them have been reported during the last few years. The types of poisoning to which they may give rise are accidental and criminal. Thus, either acute or subacute arsenical poisoning may occur, and this will be either of an accidental, suicidal, or homicidal type, or chronic arsenical poisoning may result, usually of an accidental type.

It cannot be doubted but that there has been a large increase in the number of cases of poisoning from industrial preparations of arsenic since 1908, and it appears certain that the ease with which very poisonous preparations of arsenic can be obtained for agricultural or horticultural purposes has been mainly responsible for this large increase.

The Poisons and Pharmacy Act of 1908 removed many of the restrictions with regard to the sale of arsenical preparations, and there can be no doubt but that, as a result of the increased facilities afforded by that Act for the sale of industrial preparations of arsenic, the public has been exposed to increased dangers from arsenical poisoning. It appears that the time has come when the mode of sale of these preparations should be carefully reconsidered with a view to the safeguarding of the public against risks of accidental or criminal poisoning. Reference will be made to this aspect of the subject later.

Industrial Preparations of Arsenic.

Arsenious oxide (As_2O_3), often called arsenious acid or white arsenic, is the most important compound of arsenic for industrial purposes, and forms the basis of most of the industrial preparations. It is a powerful poison, two grain being a possible fatal dose. It is a white, inodorous, almost tasteless powder, and so may be taken in food or drink without any suspicion arising from alteration in taste, smell, or colour. It has on various occasions been used in the preparation of food in mistake for baking powder, sugar, salt, cream of tartar, flour, and meal. It can be bought in any quantity from pharmacists, or from persons licensed to sell it. If sold in quantities of less than 10 lb. it must be coloured with at least one-sixteenth its weight of soot or one-thirty-second its weight of indigo. The evidence of recent notable trials show that this rule is not always followed (Armstrong case). I sold in a single quantity of over 10 lb. it is not necessary for the arsenic to be coloured if its usefulness would thereby be impaired. The provisions of the Poisons Act must of course be complied with, and the sale duly recorded in the poison register.

An easily available source of white arsenic which is often forgotten is the chemical laboratory. The poison can be obtained in any quantity from wholesale firms for laboratory purposes without any restriction as regards its sale. Every chemical laboratory possesses large quantities of white arsenic easily accessible to anyone visiting or working in it.

When arsenious oxide is used for industrial purposes it is frequently used in combination with an alkali such as caustic soda or sodium carbonate, when the very soluble sodium arsenite is produced.

Examples of its Industrial Preparations.

These include weed killers, which may be in the liquid or solid form. Liquid weed killers are strong solutions of sodium arsenite, and may contain from 14 to 40 per cent. of arsenious oxide. The solution is usually coloured by the addition of an aniline dye such as fluorescein, though during the war it was sold uncoloured. There does not appear to be any legal requirement to colour the liquid preparations. Solid weed killers are on the market and are sold in tins as a fine powder, usually coloured and containing a high percentage of arsenic. There would appear to be a legal requirement to colour this preparation. An example of the solid weed killer is "Eureka weed killer," which was mentioned in the Greenwood case. A sample was found by Mr. J. Webster to contain 60 per cent. of arsenious acid, and to be coloured by phenolphthalein. The powder was very soluble in water, and formed a pinkish-red solution which was decolorized by acids.

Arsenical weed killers are most poisonous, and not only have often given rise to accidental acute poisoning, but there is reason to believe that they have been used for criminal purposes on many occasions. An example of several cases of accidental poisoning due to liquid weed killer occurred at Haslemere in April, 1920, when a sack of sugar absorbed a quantity of liquid weed killer from a leaky tin placed beside it during transit in a railway carriage. The consumption of the contaminated sugar gave rise to an outbreak of acute arsenical poisoning. About sixty cases occurred, but no deaths ensued. In the case of *Rex v. Bingham* (1911) three fatal cases of arsenical poisoning were the subject of inquiry, and these cases were undoubtedly due to poisoning by liquid weed killer. In May, 1921, an inquest was held on a woman named Hantolow at Beckenham, where death was found to be due to acute arsenical poisoning. In this case the source of the arsenic appeared to be Eureka weed killer. In the recent Greenwood case (1920) and the Armstrong case (1921) both liquid and solid weed killers were the subject of careful investigation as regards the origin of the arsenic found in the bodies of the deceased persons.

Arsenical Wood Preservatives.

Preparations of this type are on the market and consist of solutions of sodium arsenite which are not coloured. In 1920 I investigated an interesting example of the possible dangers of arsenical poisoning from the use of these preparations. An immense wooden hut in which 2,000 girls were employed became infested with bugs, and in order to destroy them the interior of the hut was sprayed with a well-known wood preservative, and it was stated that the men who did the spraying suffered from "sores on the hands." The undiluted preparation was reported to contain 32.1 per cent. of arsenic. A month after the treatment of the interior of the hut a white incrustation was observed on the surface of the wood, and this led to suspicion and an examination of its nature. A portion of the white deposit was scraped off and was found on analysis to contain 61 per cent. of arsenious oxide. Dust from near the top of the roof of the hut contained 11.5 per cent. of arsenious oxide, and dust from a file rack contained 3.6 per cent. of arsenious oxide. The air of the hut at the level of the working tables contained an appreciable amount of arsenic (0.07 mg. per 100 cubic feet). It was obvious that there was great danger from arsenical poisoning to those working in the hut, and continued working under such conditions would be certain to be followed by an outbreak of arsenical poisoning. Prompt measures were taken for dealing with the arsenical deposit on the wood. Several washings of the whole interior with a warm solution of sodium carbonate followed by several washings with warm water were efficient in the removal of the sodium arsenite deposited on the surface of the wood. After this treatment it was found that the contamination of the air and dust of the hut with arsenic ceased, and it is interesting to record that not a single case of arsenical poisoning occurred amongst the occupants of the hut, and that their work did not have to be stopped while the cleansing processes were being carried out.

Careful statistics of illnesses which might have been due to chronic arsenical poisoning, such as gastritis, skin diseases, diarrhoea, neuritis, etc., were kept during the whole period, and medical examinations were carried out, but no instance of arsenical poisoning was discovered.

Arsenical Sheep Dips.

These are either solid or liquid preparations of a mixture of arsenious oxide and sodium carbonate or caustic soda; sometimes they contain sulphur in addition. The undiluted preparations contain a high percentage of arsenic, and numerous cases of accidental and criminal poisoning have occurred from them. The same risks apply as with weed killers. There is risk of chronic arsenical poisoning, such as arsenical skin rashes, to those who carry out the sheep-dipping process.

Fly Papers and Fly-killing Solutions.

Fly papers are prepared by soaking bibulous paper in a solution of sodium arsenite, to which is sometimes added infusion of quassia. Fly papers usually contain from 3 to 7 grains of arsenious oxide per sheet. In the Seddon case analyses were made of fly papers from five different manufacturers, and percentages varying from 3.8 to 6.6 grains per paper were found in the different samples.

Sodium arsenite in solution, mixed with sugar or treacle, is used for moistening canvas sheets or screens in order to kill flies. This method was found of great service to the sanitary departments in the war.

An instance of accidental poisoning from sodium arsenite came to my notice during the war. In 1916 a cask of sodium arsenite intended for purposes of fly destruction lost its label, and some of the material was added to drinking water in mistake for alum, the latter being necessary for the clarification of the turbid water, which was the only kind available for drinking purposes. The sodium arsenite had the effect of clarifying the water, but these who drank it suffered from symptoms of acute arsenical poisoning. Fortunately the symptoms were at once recognized and the supply of contaminated water stopped, so that no fatal case of poisoning occurred.

On September 16th, 1916, I saw a very severe case of arsenical neuritis in a soldier who had been on duty at the drinking water station, and on August 20th, 1916, had drunk freely of the contaminated water. This man had a rapid pulse (112) with some cyanosis. There was marked wasting of the muscles of the hands, feet, forearms, and legs. There was peeling of the skin of the hands and feet and some thickening of the skin of the palms and soles. The conjunctivae were also injected. He had suffered from severe diarrhoea and vomiting on August 20th and 21st, 1916.

The case is of interest and is unusual since it shows the rapid development of severe arsenical neuritis and skin lesions following the taking of sodium arsenite in solution over a period of a few hours only.

Preparations of Arsenic.

Arsenical powders, pastes, and liquids for destroying animals and insects are extensively used. The active principle of these is arsenious oxide. Thus "arsenic rat paste" is a mixture of arsenious oxide, breadcrumbs, lampblack, and glycerin. Arsenical rat powders are made with a mixture of arsenious oxide and flour, to which is sometimes added strychnine and barium carbonate. Arsenical mouse powders contain white arsenic, oatmeal, or flour, to which sugar or powdered cheese is added. Sometimes these contain strychnine in addition to arsenic. "Liquid arsenical ant destroyer" is a mixture of arsenious oxide, sugar, glucose, and water; and "arsenical ant paste" is a mixture of arsenious oxide, sugar, glucose, and flour.

Arsenical soaps and pastes, the active constituent of which is arsenious oxide, are used by taxidermists in the preservation of skins. Solutions of arsenic at one time had a reputation as cosmetics, and in the Maybrick trial this use was alleged as an explanation of the possession of arsenic by the accused. Arsenical preparations are not at present used for external application to the skin.

Veterinary Uses.

Arsenious oxide has been used by grooms and horse dealers for internal administration to horses in the belief that it improves the appearance of the coat. It is scarcely necessary to add that the unskilled use of this powerful drug is frequently attended by disastrous results to the unfortunate animals.

Fruit Tree Sprays.

Arsenical preparations are most extensively used at the present time for spraying fruit trees in order to destroy harmful insects. Arsenious oxide and sodium arsenite are too destructive to the foliage of the trees to be of value. Insoluble preparations of arsenic, such as lead arsenate or calcium arsenite, are generally used, the liquid consisting of

CURRENT NOTES.

Alteration in the Terms of Service of Insurance Practitioners.

THE object of the National Health Insurance Act, 1922, is to give statutory effect to the arrangements made between the Ministry of Health and Approved Societies whereby certain of the money now, provided by the Treasury for medical benefit shall no longer be defrayed out of the national exchequer but shall come out of the funds of Approved Societies. Provision is contained in the Act for the Ministry of Health to prescribe the conditions attaching to the payment of this money to practitioners; such conditions were hitherto contained in an agreement between the Ministry of Health attaching to what has been known as the Treasury Grant and have always been part of an insurance practitioner's agreement with Insurance Committees. On June 15th the Ministry informed the Insurance Acts Committee that as the "point" would have to be put into the law, opportunity was being taken to make various amendments to the Regulations upon a number of other points which experience had shown to be desirable, some of which had been suggested by the Committee. The Ministry furnished the Committee with a memorandum as to the effect of the proposed changes, and various suggestions were made by the Committee and were included in the draft Regulations. The draft Regulations were considered by the Committee on July 6th, when they were approved subject to two reservations which have since been met by the Ministry. The Committee has informed the Ministry that it approves the Regulations on behalf of Panel Committees and insurance practitioners, and accordingly it has no hesitation in recommending the acceptance by insurance practitioners and Panel Committees of these amendments to the Regulations. It is understood that the Ministry of Health has issued to Insurance Committees sufficient copies of the new Regulations and of an explanatory memorandum for dispatch to insurance practitioners. The Regulations as to the old Treasury Grant conditions are retrospective as from April 1st last, while the other Regulations come into operation on September 1st next.

Midwifery Engagements.

The medical profession holds that an engagement to attend a midwifery case is binding on both sides unless due notice is given, and claims that the fee is payable even if the practitioner is not present when the child is born. The reason for this is that the practitioner must of necessity keep himself free from other engagements, and must not absent himself from home at or about the time when the confinement is expected.

This contention is borne out by a decision given by his Honour Judge Moore Canu at the Eastbourne County Court. From the report in the *Eastbourne Chronicle* of August 12th we gather that in this case a doctor sued the defendant for a professional retainer fee of £2 2s., which he claimed he was entitled to recover under an agreement made with the defendant's wife in May, 1921, to attend her in her prospective

confinement expected at the end of November or the beginning of December following; the particulars of the engagement were entered on a professional card given to her at the same time.

According to the plaintiff's version of the subsequent incidents, which first came to his knowledge when he called on the wife of the defendant at the beginning of this year, in the early part of last December, when the confinement was at hand, the plaintiff's retained services were not requisitioned by the defendant, but another doctor was summoned (it is alleged at the instigation of the nurse in attendance) to assist at the completion of the confinement, and that he continued to attend the defendant's wife throughout her convalescence, and was paid by the defendant for his services. No explanation was tendered, nor cause or reason assigned by the defendant for dispensing with the plaintiff's services. At the plaintiff's last interview the defendant's wife admitted liability for his fee, which she promised to pay very shortly. As this promise was not fulfilled within a reasonable time, the plaintiff sent a written demand for payment to the defendant, who, in reply, repudiated all liability. Hence this action. After hearing the defendant's evidence, which in no essential contravened the plaintiff's statement of facts, and after listening to and reviewing the legal arguments pro and con the validity of the "agreement" as a definitely binding contract, his Honour held that the plaintiff was entitled to the full amount of his claim of £2 2s., with costs.

In this case the doctor brought the case into court solely for the purpose of reasserting the principle set out at the commencement of this note.

THE ANNUAL EXHIBITION OF SURGICAL INSTRUMENTS, DRUGS, FOODS, AND BOOKS.

(Continued from page 90.)

A LITTLE group of stands devoted to orthopaedics was a special centre of interest in the exhibition. The stand of J. E. Hanger and Company, Ltd., of Rochampton, displayed some very ingenious metal limbs for amputations below and above the knee and through the hip. A demonstration was given at this stand by limbless men, who showed the perfection of the fitting by the ease with which they used the appliance; indeed, it needed more than a casual glance to make sure that they had not the use of their natural limbs. J. F. Rowley, Ltd., also of Rochampton, exhibited a special rubber foot and other refinements, such as ball-bearing joints for the elimination of the shock or jar from which wearers of artificial appendages find it difficult always to escape. The whole exhibit proved how refined a thing the production of artificial limbs has become—that it is not a question merely of providing something in the shape of a limb, but of attending to a great number of small details which make all the difference to the comfort of the wearer and to the ease with which he can get about. Other ingenious examples of surgical mechanics were to be seen at the stand of Henders, Ltd., who exhibited various forms of foot supports, in which special attention was given to contour, and of shields and medications for foot hygiene.

The Holborn Surgical Instrument Company showed a very large number of instruments, principally for genito-urinary purposes, including various forms of urothoscopes and cystoscopes; prominence was given also to instruments for the surgery of the ear, nose, and throat, and especially to a pantoscopo for giving illumination in these examinations. The Anglo-French Drug Company, Ltd., shared a stand with Modern Pharmaceuticals, Ltd., and both firms exhibited a large number of pharmaceutical preparations. One of the most interesting things shown by the former house was a self-contained ampoule, the contents of which it was declared would keep indefinitely, for carrying "914" in solution.

The next stand was devoted entirely to ophthalmic instruments and equipment. Of the many interesting devices shown by Theodoro Hamblin, Ltd., the principal was a combined instrument for perimetry and scotometry. It was claimed as one of the advantages of this instrument that no gut or wire was used in its construction, so that it was free from certain disadvantages attaching to other mechanical types of perimeters. Some improved patterns of the Morton ophthalmoscope were also to be seen here, and special attention was directed to the reversible small mirror, and its freedom from edge reflections.

A large and varied display of surgical instruments was to be seen at the stand of Mayer and Phelps, whose exhibit included instruments for use in urology, gynaecology, and laryngology, as well as anaesthetic apparatus. Perhaps the most noteworthy exhibit on this occasion was an instrument for the examination of the oesophagus and air passages. It consisted of combined electroscopes and endoscopy tubes, with interchangeable proximal and distal lighting. Near by was a stand of more particular interest to members of the dental profession, De Troy and Company, Ltd., devoting their exhibit to hypodermic needles and to a special form of sterilizer. The hypodermic needles were made of a stainless steel so as to resist the action of all common acids; it was stated that some of the needles had been left immersed in sea water for several days, and that not the slightest tarnish was to be detected.

The claims of Buxton were advanced at a neighbouring stand, and the photographs and literature of the mountain spa and the Peak District made a very attractive display indeed. The Buxton waters in bottle were also shown. This end of the centre aisle was, indeed, a very attractive part of the exhibition. Here the Museum Galleries, of London, were showing some delightful mezzotints and stipple engravings of the works of the old masters, as well as a gallery of a hundred famous portraits, including Lord Lister and other great figures in medicine.

The uses of colour, not in art but in science, were demonstrated close at hand by the British Dyestuffs Corporation, Ltd. A dozen or more dyes designed to be used as stains for microscopic work were exhibited here. The term "purity" as applied to such stains can only be appreciated and determined by an expert analyst, schooled in the tradition of such a chemical and scientific industry as that of the manufacture of dyestuffs. All the stains prepared by the Corporation had been tested analytically in this fashion, and tested also in respect of perfect solubility, uniformity, and pathological "correctness" as well as purity. The stains shown included methylene blue, toluidine blue, basic magenta, gentian violet, methyl violet, safranin, neutral red (for staining ganglion cells), eosin, nigro blue (a stain for flagella), and a number of others. The Corporation also showed acridavine, which it has manufactured since 1917; it presented a quartar of a million grams of this substance to the British Government for use in hospitals during the war. A paper on this anti-septic was communicated to the Section of Pathology, and was published in full, with a special plate of illustrations, in the *Journal* for August 19th (p. 306).

The general anaesthetic known as "ethanecal" was the principal feature at the stand of Savory and Moore, Ltd. This is an ether preparation, containing the higher ketones, some carbon dioxide (which is thought to exercise a stabilizing influence), and some ethylene, and was described originally at a meeting of the Section of Anaesthetics of the Royal Society of Medicine last year (*BRITISH MEDICAL JOURNAL*, April 16th, 1921, p. 565). Among the other exhibits at this stand were a number of medicinal preparations, including quinine sulphate, prepared in the form of thin, pliable gelatin sheets, or "lamels," of uniform thickness, each containing an exact quantity of the drug. The firm also showed its infants' and invalids' food. Special foods were again the feature of the stand of Numol, Ltd., but some

surgical antiseptics were also shown, including a solution for the sterilization of surgical instruments. The preparations of the Maltine Manufacturing Company, Ltd., were shown at another stand, these including the original "maltine," plain and in various combinations, and a later introduction under the name of "maltoline," which is a combination of "maltine" with other constituents; it is supplied in a palatable powdered form with a view to its use in diseases of malnutrition.

The mineral waters shown by Ingram and Royle, Ltd., included samples from almost every European spa, but the first place was still given to the water and salt of the Vichy springs in France. Gaymer's cyder, ready in the glass, accounted for a refreshing corner, and many visitors sampled this Norfolk beverage. A neighbouring stand was devoted to perfumery, in the shape of the floral disinfectants of the Cromessol Company, of Glasgow, in which the attars of flowering plants were used for obtaining the various odours. Disinfectant perfumery is carried to its limit when it is suggested that in a cinematograph hall or theatre a particular odour can be used in consonance with the picture or scene presented.

One of the few stands to show x ray and electro-medical equipment was that of Schlatt and Son, where the principal exhibit was an apparatus for deep therapy, suitable for passing a current of 3 milliamperes continuously through a gas-filled tube with an equivalent spark-gap of 16 inches, or a Coolidge tube with one of 20 inches, for eight hours a day, which prolonged exposure may be necessary in the treatment of carcinomas in a single sitting. Allied with this was a couch for deep therapy with an overhead gear, by means of which the tube-box could be adjusted in any position with regard to the patient lying below.

(To be continued.)

Association Notices.

COUNCIL, 1922-23.

(a) VACANCIES.

NOTICE is hereby given of the following vacancies in the membership of the Council:

- (i) *Glasgow and West of Scotland, four City Divisions* (one of the "24"), owing to no nomination having been received at the time of the annual election;
- (ii) *Manchester Branch* (one of the "24"), owing to no nomination having been received at the time of the annual election;
- (iii) *Glasgow and West of Scotland, Border Counties, and Stirling Group of Branches* (one of the "12"), owing to no valid nomination having been received at the election during the Annual Representative Meeting;
- (iv) *Metropolitan Outer Group* (one of the "12"), owing to the resignation of Dr. H. B. Brackenbury, consequent upon his now, as Deputy Chairman of the Representative Body, being a member of the Council *ex officio*; and
- (v) *Indian Group*, comprising the Assam, Baluchistan, Bombay, Burma, Ceylon, Hyderabad and Central Provinces, Mesopotamia, Punjab, and South Indian and Madras Branches, owing to the resignation of Lieut.-Colonel R. H. Elliot, I.M.S. (ret.).

Under now By-law 54 (2) the Council is empowered either to fill the vacancies itself or cause them to be filled by means of an election by the Body authorized to elect, and has decided to adopt the latter course in the present cases.

(b) NOMINATION AND VOTING.

(i) Home Areas.

NOMINATIONS in respect of vacancies (i) and (ii) above (i.e., in the "24") require to be either (a) by a Division comprised in the Group in question, or (b) by not less than 3 Members of any such Branch.

NOMINATIONS in respect of vacancies (iii) and (iv) above (i.e., in the "12") must be by a Representative of one of the Constituencies comprised in the Group.

FORMS of NOMINATION will be forwarded on application to the Medical Secretary, 429, Strand, and should be returned so as to reach him not later than Saturday, September 16th, 1922.

In the event of more than one candidate being nominated for any vacancy, VOTING PAPERS will be issued to the electors concerned on September 29th, and should be returned so as to reach the Medical Secretary not later than first post on Friday, October 6th.

The result of the elections will be published in the *British Medical Journal Supplement* of October 14th, 1922.

(ii) Area Outside United Kingdom.

NOMINATIONS in respect of the Grouped Indian Branches must be signed by not less than 3 Members of any Branch in the Group, and must be in the following form, or in one to the like effect, and should be received by the Medical Secretary not later than Saturday, November 25th, 1922:

COUNCIL, 1922-23.

NOMINATION FORM FOR ELECTION OF A MEMBER BY THE
GROUPED INDIAN BRANCHES.

By Not Less than 3 Members of the Grouped Indian Branches.

We, the undersigned, hereby nominate
of (Full name and address to be given)
for election by the Assam, Baluchistan, Bombay, Burma, Ceylon,
Hyderabad and Central Provinces, Mesopotamia, Punjab, and
South Indian and Madras Branches as a Member of the Council
of the Association for the Session 1922-23.

Signatures and Addresses of Nominators

Branch(es)

Date 1922.

The election, if a contest occurs, will be by VOTING PAPERS, containing the names of all duly nominated Candidates, issued from the Head Office, 429, Strand, London, W.C.2, to each Member of each Branch in the Group.

ALFRED COX, Medical Secretary.

BRANCH AND DIVISION MEETINGS TO BE HELD.

YORKSHIRE BRANCH: HARROGATE DIVISION.—A meeting of the Harrogate Division will be held at Y.M.C.A., Harrogate, on Saturday, October 7th, at 5 p.m., when Dr. Gordon Holmes will deliver a British Medical Association lecture on Some of the Clinical Manifestations of Tabes, which will be illustrated by lantern slides.

Meetings of Branches and Divisions.

EDINBURGH BRANCH.

The annual meeting of the Edinburgh Branch was held at Galashiels on June 21st, with Dr. W. STEWART, President, in the chair. At the conclusion of the luncheon in the Douglas Hotel the President proposed that a Branch Golf Club should be instituted, which was unanimously agreed to, the President being elected *ex-officio* captain, and Dr. J. M. Bowie secretary. The afternoon from 1.30 to 4.30 was devoted, at the choice of the members, to a golf competition, bowling, and a motor drive by Barmersyde to Dryburgh Abbey and back by Melrose. At 4.30 p.m. the members of the South-Eastern Counties Division entertained the company to tea in the Technical College, and the business meeting of the Branch was afterwards held, being attended by some forty members. The President proposed: "That the new Rules of Organization of the Branch, submitted by the Branch Council in draft, be adopted as the Rules of Organization of the Branch, in substitution for the Rules of Organization dated 1904." This was unanimously agreed to, and the new Rules of Organization came immediately into effect. The action of the Branch Council in nominating Dr. J. M. Bowie and Mr. H. Wade to serve on the Local Voluntary Hospitals Committee for the Lothians and Peebles under the Voluntary Hospitals Commission was unanimously approved. The treasurer submitted his annual report, which was approved, and Dr. W. Stewart was elected a trustee in the place of the late Professor Boyd.

The following office-bearers, nominated by the Branch Council, were unanimously elected:

President: Dr. J. S. Muir. President-elect: Dr. W. R. Martine. Past President: Dr. W. Stewart. Vice-Presidents: Dr. J. Playfair and Dr. J. Lamond Lackie. Honorary Treasurer: Dr. R. Thin. Honorary Secretary: Dr. J. Stevens. Assistant Honorary Secretary: Mr. F. E. Jardine.

Dr. J. S. Muir was then installed as President, and in his introductory remarks gave reminiscences of the history of his Division from the time he became a member. Dr. THIN proposed a cordial vote of thanks to Dr. Stewart for his services as President during the past year, which was given with acclamation. It was intimated that Dr. C. M. Pearson had been elected to represent the Edinburgh and Fife Branches on the Council of the Association for 1922-23, in succession to Dr. John Stevens, whose six years' period of office in that capacity had expired. Dr. J. Haig Ferguson was elected to the annual vacancy on the Board of Management of the Queen Mary Nursing Home in place of the retiring member, Dr. William Fordyce. Dr. MARTINE proposed a vote of thanks to the honorary secretary, Dr. John Stevens, for his services, which was cordially agreed to, and the SECRETARY replied expressing his acknowledgement of the compliment.

NORTH WALES BRANCH.

A MEETING of the North Wales Branch was held at Menai Bridge on July 11th. The President, Dr. H. DRINKWATER (Wrexham), introduced the President-elect, Lieut.-Colonel H. JONES-ROBERTS, who took the chair. The report of the Branch Council was read and approved, and the model Ethical rules were adopted without modification. The model Organization rules were considered, and, with some alterations, were adopted.

The PRESIDENT delivered his address on "A review of the history of the Branch from its formation in 1849." He recalled that in 1849 at the annual meeting the Council of the Branch was con-

gratulated on the passing of the Medical Act, which included the registration of all duly qualified medical men, and registration societies were formed all over the country. But the Medical Act did not satisfy the members of the Association, and several forcible resolutions were passed, including one suggesting that chemists and druggists should be prohibited from visiting the sick and prescribing for them. The opinion was also expressed that the doctrines of homoeopathy were based on erroneous and false data, were the product of ignorance, and were dangerous to public health, and that it was the duty of all qualified members on no account to meet practitioners of that system in consultation. In 1869 a case of fracture, dealt with "under Dr. Lister's method," was brought forward, regarding which the report was rather qualified. In 1873 the Branch was entitled to three members on the Council, while at the present time it was not entitled to one; this was an injustice, he considered, not only to the Branch, but to the Principality. In 1875 reference was made at the annual meeting of the Branch to the resignations of their posts as quarry-doctors at Dinorwic and Penrhyn (Bethesda) of two members of the Branch rather than accept the services of an unqualified bonesetter. In 1877 a petition was signed against the admission of women members of the British Medical Association, it being observed that if females were allowed to enter it was very desirable that their education and examination should be conducted separately from the males, and they should be placed in a separate department of the Register, similar to that of foreign degrees! In conclusion, the President said that lessons were to be learned from a review of the past. The loyalty of the old members to the Branch was remarkable. They had no motor cars or fast trains in those early days, and had to do much hard work on horseback. Yet they attended the Branch meetings, and withal found time to keep themselves abreast of the times. The British Medical Association was not yet what they wished it to be. They should have better and closer association between the Branches and the Council. Every Branch, he believed, should be represented on the Council by a member of the Branch and not by the group system.

Another lesson to be learned from the history of the past was that their forefathers possessed a high sense of honour. They lived in a different age to-day. But it was well to remember that in spite of all changes of circumstances and time that the honour and prestige of the profession was a sacred trust handed down to them, which they in turn must hand down unsullied and undimmed.

On the motion of Dr. ROBERT PARRY (Carnarvon), seconded by Dr. HUGH JONES (Dolgelly), the President was cordially thanked for his inspiring address.

Dr. JOHN HAY of Liverpool then delivered a British Medical Association lecture on "Cardiac failure." In the discussion which followed, several members took part, and Dr. Hay replied. A hearty vote of thanks to Dr. Hay was carried with acclamation.

After the meeting the members were entertained to tea on the hotel lawn by the President.

During the meeting, which was very successful from every point of view, a leaflet, prepared by the President, was circulated containing the names of all the Presidents and officials of the Branch from 1849 to the present time.

EXAMINATIONS UNDER THE DENTISTS
ACT, 1921.

WE have received from Colonel Norman King, Registrar of the Dental Board of the United Kingdom, a table of the results of the first series of examinations under the new Act, which took place last month in London, Manchester, and Edinburgh. Part 1 includes a written paper and an oral examination; Part 2 the practical examinations in operative dentistry and dental mechanics. It is interesting to note that the majority of those who failed did so in Part 2, which included the subjects in which they claimed to be proficient, and not in Part 1, with regard to which most of them seemed to have the greater anxiety. The table printed below is a summary of that supplied by Colonel King, in which the candidates were classified under the headings "Mechanics," "Practitioners," and "W. S. Candidates"; the separate figures were also given for the three cities in which the examinations were held.

	No. of Candidates.	Passed.	Failed.		
			Part 1.	Part 2.	Parts 1 & 2
Mechanics	111	86	9	12	4
Practitioners	55	41	3	8	3
"W. S." candidates ...	68	47	5	10	6
Total	234	174	17	30	13

"W. S." candidates are those who were unable to show five years of practice exclusive of war service, and were admitted to examination without fee and with certain other advantages. If they fail in one part of the examination they are allowed to take that part afterwards by itself, but this

concession is not made to those who are not within this category. It will be seen by the table that ten "W. S." candidates will have to take Part 2 again, five will have to take Part 1 again, and those who failed in both parts will have to take the whole examination again. Section 3 (1) of the Dentists Act, 1921, states that the Board shall admit to the *Dentists Register* "any person who makes an application in that behalf within the interim period and satisfies the Board that he is (i) of good personal character; and (ii) was for any five of the seven years immediately preceding the commencement of this Act engaged, as his principal means of livelihood, in the practice of dentistry in the British Islands, or was admitted to membership of the Incorporated Dental Society not less than one year before the commencement of this Act; and (iii) had attained the age of twenty-three years before the commencement of this Act."

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following announcements are notified by the Admiralty: Surgeon Captain K. T. Meagher to the *Fird*, for R.N. Hospital, Plymouth; H. S. Burniston, C.M.G., to the *Fird*, for R.N. Hospital, Surgeon Commander R. Willa to the *Pembroke*, for R.N. Hospital, Surgeon Lieutenant Commander J. D. S. Higgins to the *Barham*, A. C. Paterson in the *Pembroke*, for Royal Marines, Deal, Surgeon Lieutenant H. L. Priddle to the *Ladybird*, and for group; K. A. T. Mackenzie to the *Queen Elizabeth*. Surgeon Commander A. J. Wernet is placed on the retired list at his own request, with the rank of Surgeon Captain.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel (Temporary Colonel) W. P. Gwynn, C.M.G., from R.A.M.C., to be Colonel, vice Colonel C. R. Pollock, C.B., C.B.E., D.S.O. (promoted), June 1st, 1922 (substituted for notification in the *London Gazette* of August 1st, 1922).

Major T. W. Stallybrass is restored to the establishment. Captain H. A. Cronch, M.C., from the half pay list, is restored to the with precedence next below W. E. K. Coles in the *London Gazette*, July 25th, 1922. Inquisit their commissions: Temporary and is granted the rank of Major; C. A. Meaden, and retains the rank of Captain.

ROYAL AIR FORCE MEDICAL SERVICE.

Dr. J. G. F. Heal is granted a short service commission as a Flight Lieutenant, with effect from, and with seniority of, August 1st, 1922. The following are granted temporary commissions as Flight Lieutenants, with effect from, and with seniority of, August 1st, 1922: M. Coghlan, J. W. H. Steil.

VACANCIES.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.—House-Surgeon (non resident). Salary, £200 per annum.

BOSTON COUNTY HOSPITAL.—Assistant School Medical Officer and Assistant Medical Officer of Health. Salary, £600 per annum, rising to £750.

BOURNMOUTH: ROYAL VICTORIA AND WEST HANTS HOSPITAL (Bournemouth Branch).—Resident Medical Officer. Salary, £175 per annum.

BRISTOL EYE HOSPITAL.—House-Surgeon. Salary, £150 per annum.

BRISTOL GENERAL HOSPITAL.—(1) Two House-Physicians. (2) House-Surgeon. (3) Casualty House-Surgeon. (4) Obstetric Officer and House-Surgeon. Salaries at the rate of £150 per annum.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, W.C.—(1) Surgical Registrar (honorary). (2) House-Surgeon, salary £75 per annum. (3) Clinical Assistants.

GUILDFORD: ROYAL SURREY COUNTY HOSPITAL.—House-Surgeon. Salary, £150 per annum.

GUILDFORD UNION.—Medical Officer of the Institution. Salary, £175 per annum and extra fees.

KNOWLE MENTAL HOSPITAL, Farnham.—Third Assistant Medical Officer (male). Salary, £300 per annum, rising to £350.

KNOWLE MENTAL HOSPITAL.—(1) Resident Medical Officer. (2) Resident and Robert Arthington Hospitals. (3) House-Surgeon. Salary, £200, £63, and £50 per annum.

KNOWLE MENTAL HOSPITAL.—Assistant Medical Officer. Salary, £400 per annum.

LONDON TEMPERANCE HOSPITAL, Hampstead Road, N.W.—(1) House-Surgeon. (2) Casualty Officer. Salary, £200 and £100 per annum respectively.

MANCHESTER CITY COUNCIL.—Third Assistant Medical Officer at the Mossall Fever Hospital. Salary, £250 per annum.

MANCHESTER: ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Resident Obstetric Surgeon. Salary, £250 per annum.

MARGATE: PRINCESS MARY'S HOSPITAL FOR CHILDREN, Cliftonville.—Junior Assistant Medical Officer. Salary, £122 per annum and bonus.

METROPOLITAN ASYLUMS BOARD.—Junior Assistant Medical Officer at the Downs Hospital for Children, Sutton. Salary, £478 per annum, with war bonus.

NEWCASTLE-UPON-TYNE: UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Senior Demonstrator of Anatomy. Salary, from £600 to £700 per annum.

NOTTINGHAM GENERAL DISPENSARY.—Resident Surgeon (Branch). Salary, £300 per annum.

PERTH: MURRAY ROYAL ASYLUM.—Assistant Physician (male). Salary, £50 per annum.

PORTPATRICK PARISH COUNCIL.—Medical Officer. Salary, £110 first year, rising to £120 second year.

POTTSVILLE HOSPITAL, S.W.—Resident Medical Officer. Salary, £150 per annum.

QUEEN MARY'S HOSPITAL FOR THE LAST END, Stratford, E.—House-Surgeon. Salary, £150 per annum.

ROCHESTER: ST. BARTHOLOMEW'S HOSPITAL.—House-Physician. Salary, £200 per annum.

ROTHESMITH HOSPITAL.—Junior House-Surgeon (male). Salary, £150 per annum.

ROYAL NORTHUMBRIA HOSPITAL, Holloway, N.—Anaesthetist. Honorary £10 10s. per annum.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Laboratory Research Worker. Salary, £500 per annum.

WEST LONDON HOSPITAL, Hammersmith Road, W.—(1) House-Physician (2) Two House-Surgeons (male). (3) Non resident Casualty Officer. Salary for (1) and (2), £100 per annum each, and for (3) £5 5s. a week.

WESTMINSTER HOSPITAL, S.W.—Medical Registrar and Casualty Medical Officer. Honorary, £150 per annum.

YORK CITY COUNCIL.—Assistant Medical Officer of Health and Assistant School Medical Officer (female). Salary, £500 per annum, or £100 resident in Maternity Hospital.

CERTIFYING FACTORY SURGEONS.—The following vacant appointments are announced: Clebury Mortimer (Salop); Patterdale (Westmorland).

This list of vacancies is compiled from our advertisement columns where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS.

IMMEDIATE ROYAL EYE AND EAR HOSPITAL.—Honorary Ophthalmic Surgeon: J. Duff McCulloch, M.B., Ch.B., Glas. Honorary Aural Surgeon: J. Duff McCulloch, M.B., Ch.B., Glas.

LIBERTY.—The following appointments are made under the Workmen's Compensation Act, 1906, at Circuit No. 20, and to the following: Harborough, and Moulton Newbury County Courts.

WIMBORNE, Thomas J. T., M.D., T.C.D., L.M. Bot., Medical Officer of the No. 4 District of the Mansfield Union.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

WILSON, Arthur J., M.B., Ch.B., Edin., House-Physician and Surgical Officer, Warwickshire Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTHS.

ANDERSON.—August 17th, at 37, Clarendon Gardens, W.2, to the wife of H. Graeme Anderson, M.D., Ch.B., F.R.C.S., of 75, Harley Street—a daughter.

DAVIDSON.—On 17th August, at Avonleigh, Acadia Road, Torquay, to Ivy, the wife of Dr. W. Cameron Davidson—a daughter.

JONES.—On 14th of August, 1922, at Bryn-y-Dre, Bangor, N. Wales, to the wife of Dr. Fowick Jones—a daughter.

MARRIAGES.

GIBSON.—PALMER.—August 3rd, at St Botolph's Church, Worthing, by the Rev. J. P. Fawcett, M.A., Dr. Charles Gibson, eldest son of the late Dr. Charles Gibson, J.P., of Hartgate, to Myra Sarah, elder daughter of Mr. and Mrs. J. R. C. Palmer, Coniston, St. Botolph's Road.

DEATHS.

LYTLE.—At a nursing home in Brighton, August 13th, James Flaw Lytle, M.D., M.Ch., M.A.O., late of Garthmore, Greigien, Court Royal Hotel, Brighton.

TAPLIN.—On the 15th of August, at Nice, Dr. Julian Taplin.

WARREN.—On the 17th of August, at 1, Lodge, Enfield Highway, Middlesex, Dr. Warren, L.R.C.S., L.R.C.P. Edin., D.P.H. Dublin, M.O. H. for Enfield, aged 62.

a fine suspension in water of the active substance. The combination of arsenic and copper, as exists in the preparation known as "Paris green" or "Schweinfurth green," is of especial value for fruit-tree spraying, since it combines the insecticidal properties of arsenic with the fungus-destroying properties of copper salts.

Perhaps the arsenical spraying liquid in most common use at the present time is lead arsenate. It is prepared by mixing a solution of lead acetate with a solution of sodium arsenate in the required proportions, and the fine suspension of the insoluble lead arsenate is used as a spray for fruit trees. The lead arsenate spray is applied by means of a spraying engine to the trees in the spring and early summer. A man using a spraying engine will be engaged in this occupation for several weeks, and in the process it is impossible for him to avoid the inhalation of the spray and to avoid its contact with his skin. Spraying is done before the leaves come out, and before the bloom comes, and also after the petals have fallen from the bloom. I have reason to believe that poisoning from lead arsenate fruit-tree sprays is fairly common in districts where this method of treatment is in use. Two interesting cases of poisoning from fruit-tree sprays have been under my care where severe illness, and in one case a fatal result, occurred.

CASE I.

F. W., a man, aged 40, was first seen by me on November 6th, 1919. He had lived in a fruit-growing district in the East of England and had followed the occupation of market gardener for many years. He had used in the spring of every year a spray for his fruit trees containing lead arsenate. For the last seven years he had been troubled with an erythematous rash on the hands and face. In April, 1919, the skin eruption became worse and was accompanied by marked swelling of the face and eyelids. In 1913 he was operated on for appendicitis, but previously had enjoyed good health. On November 6th, 1919, I found a marked erythema of the dorsum and palms of the hands and some thickening of the nails and tenderness of the finger-tips, and erythema and swelling were present on the face and neck. The patient stated that this condition had been present since April, 1919. On the face and neck and ears some exfoliation was present and also patches of brown pigmentation.

My colleague, Dr. Graham Little, saw this patient with me in November, 1919, and showed the case at the Dermatological Section of the Royal Society of Medicine in that month. On November 6th the urine was of specific gravity 1014, albumin was present in considerable amount (1/10 on boiling), and epithelial and granular casts were found. On November 27th the urine was found by Mr. J. Webster to contain arsenic in amount 1/200 mg. per 100 c.c.m., and the hair contained a considerable proportion of arsenic, 2.8 mg. per 100 grams.

On March 3rd, 1920, in spite of the utmost precautions to avoid any contact with arsenical sprays, the urine was found to contain traces of arsenic, 1/500 mg. in 100 c.c.m. In the middle of March, 1920, the patient came to reside in London for a few weeks so as to be away from any possible absorption of arsenic. On March 25th the urine still contained 1/20 albumin on boiling, but was now free from arsenic. On April 6th there was considerable improvement in health; the urine was free from albumin, and contained no arsenic. The patient returned home in April, 1920, and soon became worse.

On July 20th he was admitted to St. Mary's Hospital under my care. At this time the skin eruption had become altered, there being marked swelling of the face, eyelids, and skin around the ears, with brown discoloration and desquamation. The axillae had also become involved, and the affected skin in this region and on the face and neck showed a commencing vesicular eruption with sero-purulent discharge. There was also a discharge from each ear, due to involvement of the skin of the external auditory meatus. The skin of the lower part of the back showed desquamation and brownish pigmentation. The hands on the dorsal and palmar surfaces were red and painful, and the skin showed desquamation. Dilatation of the heart was present, and the urine contained albumin. The patient only remained in hospital for four days, and returned home at his own request. His condition became gradually worse, and he died on September 22nd, 1920.

I have no doubt that the illness of this patient was due to chronic arsenical poisoning caused by absorption of lead arsenate from the spraying preparations with which he had been in contact for years. The temporary disappearance of albuminuria in April, 1920, when there had been freedom from possible absorption of arsenic for a few weeks, is characteristic of arsenical albuminuria. It is probable also that the marked pathological affection of the kidneys was partly contributed to by the lead present in the arsenical spray.

CASE II.

A man, aged 44, a working fruit grower, who had used lead arsenate sprays for several years, was first seen by me on December 11th, 1919. He gave a history of epigastric pain and nausea since August, 1919. In October, 1919, attacks of running of saliva from the mouth occurred. These attacks occurred about once a week, and lasted from twelve to fifteen hours. During an attack the patient would discharge from 4 to 7 pints of salivary

excretion. On December 11th, 1919, the urine was analysed by Mr. John Webster and found to contain a considerable trace of arsenic, 1/40 mg. in 100 c.c.m.

On February 13th, 1920, a specimen of urine was again examined and found to contain 1/300 mg. of arsenic in 100 c.c.m. The salivary excretion passed at this time contained no arsenic. On February 25th the urine still contained arsenic, in amount 1/600 mg. per 100 c.c.m. On June 4th the urine was again examined and was found to contain a considerable amount of arsenic, 1/50 mg. per 100 c.c.m. This patient had no albuminuria or skin rashes, and beyond the gastric symptoms and paroxysmal hyperptyalism showed no symptoms of chronic arsenical poisoning. I have no doubt that the paroxysmal attacks of hyperptyalism were due to chronic arsenical poisoning, but I do not know of any previously recorded cases.

Calcium arsenite is made by boiling a mixture of water, arsenious oxide, and quicklime together; the suspension of the calcium arsenite produced, when appropriately diluted, has been found to be an efficient spraying liquid for fruit trees.

London purple is a coloured arsenical residue obtained in dyeworks; when mixed with lime and water it forms an effective spraying liquid which owes its efficiency to the calcium arsenite present. Paris purple is a similar preparation.

Scheele's green (copper arsenite) when mixed with water has been used for fruit-tree spraying. Since it is destructive to the foliage its use has been almost abandoned.

Paris green, also known as Schweinfurth green, emerald green, mitis green, or French green, is copper aceto-arsenite. It is prepared by mixing boiling solutions of arsenious oxide and copper acetate, when the Paris green is precipitated as a fine green powder which is practically insoluble in water. The suspension of this powder has been extensively used for fruit-tree spraying. Owing to its insolubility it is not destructive to foliage, and by virtue of the arsenic and copper present it has both insecticidal and fungus-destroying properties.

Preparations Formerly Used.

Arsenical pigments such as Scheele's green, Paris green, and the sulphides of arsenic were at one time much used for colouring wall-papers, artificial flowers, etc. Owing to their poisonous properties these substances are fortunately rarely used for such properties at the present time.

Arsenic tri-sulphide was at one time used as a dopilatory, but since certain non-poisonous mixtures are more efficacious its use for such purposes has been abandoned.

Metallic arsenic powder known as "cobalt" was at one time used for killing flies. Its virtues were due to the presence of the arsenious oxide produced by oxidation in the air, and the substance often gave rise to accidental or criminal poisoning. Its use has been abandoned in this country for many years.

Arsenious oxide and other arsenical compounds are used in many commercial manufacturing processes other than those mentioned, and in such uses they may give rise to arsenical poisoning in the workers. The consideration of these risks would be outside the scope of this paper.

Arseniuretted Hydrogen Poisoning.

The dangers to health from arseniuretted hydrogen poisoning have been very fully dealt with by our President, Professor Glaister, in his admirable work on the subject. Mention must also be made of the risk of poisoning by the mixture of arseniuretted hydrogen and phosphoretted hydrogen which results from the action of moisture on the preparation known as ferro-silicon, which is imported from Germany for the purpose of hardening steel. The very careful regulations made by the Home Office and Board of Trade regarding the precautions necessary for the transport of this substance have been most successful in removing risk of poisoning. (Vide H. Wilson Hake, *Lancet*, July 23rd, 1910.)

The Contamination in Transit of Foodstuffs with Arsenical and other Poisons.

In consequence of the occurrence of numerous cases of poisoning due to the contamination in transit of articles of food by poisonous substances such as liquid weed killer, liquid sheep dip, etc., the Ministry of Health, in April, 1919, recommended the railway companies to increase the stringency of regulations relating to the carriage of those dangerous substances. It was decided that in future these poisonous substances should only be accepted for transit when contained in iron cans or drums of between five and fifty gallons capacity, securely closed so as to prevent leakage, and on no account should they be allowed to be conveyed by rail in wooden casks. Previously to the war, regulations were in force by the railway companies which ensured the transit of poisonous

substances in separate wagons, but since the war, owing to the dearth of rolling stock, this has not been possible. On August 10th, 1920, notice was given in the *London Gazette* of a new regulation to supersede No. 14 of the regulations made under Section 2 of the Poisons Act, 1908. The new regulation was as follows:

"A poisonous substance shall not be sold except in an enclosed vessel or receptacle as received from the manufacturer, which vessel or receptacle must be of sufficient strength to withstand rough usage, securely closed, and free from leakage, distinctly labelled with the name of the substance and the word 'Poison,' and with the name and address of the seller, as provided by Section 17 of the Pharmacy Act, 1868, and also with a notice of the special purpose for which it has been prepared. For the purposes of this Regulation the person on whose behalf any sale is made shall be deemed to be the seller."

The Sale of Industrial Preparations of Arsenic.

By the Sale of Poisons Act, 1868, the sale of arsenical preparations used for industrial purposes was only permissible by qualified pharmacists. The Poisons and Pharmacy Act of 1908 removed many of the restrictions relating to the sale of these preparations, it being then thought that certain advantages might accrue to the public from the greater freedom for purchase, and it was not at that time realized that these advantages might be accompanied by serious and grave dangers. By Section 2 of this Act it was enacted that "poisonous substances to be used exclusively in agriculture or horticulture for the destruction of insects, fungi, or bacteria, or as sheep dips or weed killers, which are poisonous by reason of their containing arsenic, tobacco, or the alkaloids of tobacco," may be sold by persons possessing no pharmaceutical qualification, provided that they are duly licensed by a local authority, and regulations were framed which dealt with the sale of these substances under such conditions.

Fourteen years have elapsed since the passing of this Act, and the time has come when the effect of the provisions of Section 2 of the Act may be carefully considered in the light of a fairly long experience. As would be expected, no serious objection can be offered to the sale of tobacco preparations, since their smell and taste are sufficient safeguards against the risk of poisoning. In the case of arsenical preparations sold under Section 2 of the Act it must be conceded that very serious and grave dangers to the public have resulted. A large number of fatal cases of accidental and suicidal poisoning have resulted from the removal of some of the previous restrictions relating to the sale of arsenical preparations used in agriculture and horticulture, and there is reason to believe that in not a few instances these preparations have been used for criminal purposes.

Dangers to the Public.

It must be admitted that persons who have had no proper training in the uses and dangers of poisons cannot appreciate the dangers likely to occur from their use, nor can they understand the necessity for special care in the storage of such poisonous preparations. Such persons are not capable of deciding whether an arsenical preparation is likely to be used for a legitimate purpose by an intending purchaser, nor can they with the confidence of experience warn such a purchaser of the dangers from poisoning of the article which they are selling. They probably have much less knowledge on this subject than the person who is desirous of purchasing from them an arsenical preparation, and could therefore not be expected to utter any warning.

The foundation principle of the sale of poisons should be that the seller has had an adequate training, and has a sufficient knowledge of the dangerous properties of the article which he is selling—in other words, he should be a proper and competent person for such sale. This foundation principle is quite destroyed by the provisions of Section 2 of the 1908 Poisons Act.

It is a very dangerous principle to assume that poisons when packed and labelled such as "weed killers" or "sheep dips" can safely be sold and distributed like articles of ordinary merchandise. The dangers to the public from the sale of industrial preparations of arsenic have during the past fourteen years been proved to be so great that it appears to me that the time has come for the safeguarding of the public against the dangers of arsenical poisoning.

Suggested Safeguards.

The first safeguard is that the sale of arsenical preparations should be limited to properly qualified and competent persons—namely, to registered pharmacists—as sellers. A second and

important safeguard would be that the sale of dangerous poisons, such as the industrial preparations of arsenic, should be limited to purchasers who obtain a licence for the possession of such dangerous articles. A tin or packet of weed killer or sheep dip is at least as dangerous a possession as a firearm, and the number of persons requiring such articles is not great. It would be little hardship to them and a very great safeguard to the public if persons requiring to use industrial preparations of arsenic were required to obtain a licence for the possession of these dangerous substances. It would be quite certain that were such an enactment made a law then very much greater care would be taken by those possessing poisonous preparations of arsenic, and the risks from arsenical poisoning would almost entirely disappear.

DISCUSSION.

Sir THOMAS OLIVER said that he was struck by the large amount of industrial arsenical poisoning which was taking place in this country. We were familiar with its frequency where arsenico-copper solutions were sprayed upon vines, and the skin eruptions on the hands of market gardeners as the result of handling soil, which we knew often contained arsenic. Sir William Wilcox had drawn attention to paralysis in acute arsenical poisoning, which was rather unusual and served to remind him of a similar series of symptoms, but due to another cause, which occurred in a youth who fell while carrying a barrel of red lead. The barrel burst and he was enveloped in a cloud of red dust. Sir Thomas Oliver then alluded to the immunity to arsenic acquired by the Styrian peasantry. The Tyrolean peasantry commenced with small doses to improve their vitality and found that this gave them greater respiratory powers in climbing the mountains.

The following resolution, proposed by Professor GLANZMANN and seconded by Dr. RUXTON, was carried unanimously:

That the sale of arsenical preparations included under Section 2 of the 1908 Act should be limited (1) on the part of the seller to properly qualified and competent persons—namely, to registered pharmacists; and (2) on the part of the purchaser to those who had obtained a licence for the possession of such dangerous articles.

SOME FACTORS WHICH MAKE FOR EFFICIENCY AND FOR THE SOCIAL UPLIFTING OF INDUSTRY.

BY

SIR THOMAS OLIVER, M.D., F.R.C.P.,

Professor of the Principles and Practice of Medicine, University of Durham; and College of Medicine, Newcastle-upon-Tyne.

The subject of "industrial efficiency" can hardly be discussed without its obverse "industrial inefficiency." There can be no industrial efficiency without healthy workpeople, and the conditions under which labour is carried on being hygienic. Men must be fit for their job, and those who are fit must be kept fit. Physical ability is the outcome of several circumstances co-operating towards a common end. There can be no dissociation of employment from home life and the manner in which leisure hours are spent. Public health has already achieved much in regard to the housing of the people, the provision of adequate supplies of drinking water and healthy surroundings, also by inspection of dairies. Public health has added to the longevity of the race; it has averted epidemic disease, diminished the death rate, and improved the chances of infantile life. Its advocates have acted upon the assumption that prevention is better than cure. What public health has accomplished industrial hygiene, its twin sister in the department of preventive medicine, is making an effort to attain. For the moment we are concerned with the individual and his employment. It is the function of industrial hygiene to see that work is carried on under the healthiest conditions possible, and that the dangers incidental to occupation are either removed or reduced to a minimum. Since work is service rendered to humanity as a whole its influence ought to be uplifting. To-day there are few trades which can be regarded as degrading, but it was not always thus—as, for example, in the early part of last century, when women, employed about coal mines, dragged like beasts of burden trucks of coal, and when men were engaged for long hours on end in the puddling of iron. I remember visiting a large ironworks in the north of Europe one evening close upon midnight. The darkness was only broken by the flare gleaming

from the numerous furnaces in which the iron was being smelted. In the lurid light thus emitted there could be seen, flitting about like demons, the workmen clad only in a tunic. There were two shifts of work—a day and a night shift, of twelve hours each. The fires were never extinguished, except when the furnaces required repairing. The men had no weekly day of rest—Sunday was the same as any other day. Only once a year, on Christmas Day, were the fires allowed to become low. The heat from the furnaces was intense, the work was hard, and as a consequence the men were old and obliged to give up work before they reached the age of 40. The company owned scores of miles of land, and when the men were no longer able to work the firm granted them gratis the use of a piece of land, part of which they could till and the other use for pasture. For a precipitated old age and corresponding physical infirmity the beneficence of the employers, considerate as it might be regarded, was after all but a poor recompense for the best years of life spent, but broken, in the service of the company, and with nothing therefore for the men to look forward to. Years of hard and unrelenting toil had taken the soul out of these men and left them physical wrecks. I plead for the uplifting influence of work, and that through it the standard of mankind may be raised, also for the dignity of labour of which our Scottish poet Burns sang. Since his day methods of work have changed. The subdivision of labour and the introduction of machinery on an ever-growing scale have abolished craftsmanship, so that it is given to few men to see the finished article towards the production of which they have contributed. Work has thus been robbed of one of its incentives. However much it may be admired the artificers can take little artistic pride in an article in the completion of which machinery, and not the personality of the worker, has played the greater part. While the individuality of the worker has thus to some extent disappeared, it is for us to see that the monotony of factory labour is reduced to its lowest level. There are certain occupations which instead of infusing the worker with enthusiasm rather tend to depress and unduly fatigue him.

The fact that men and women are physically affected by the trade which they follow raises the question as to whether working men should be periodically medically examined. There are three points of view at least from which this subject may be approached: (1) the attitude of the workman concerning his rights, to which he would probably subordinate all questions concerning his health and his industrial future; (2) the attitude of the employer; and (3) the general medical aspect of the question. I do not think that the working men themselves would accept medical examination on the lines which have hitherto been proposed. If this is the case, then it would be difficult to make an examination compulsory. Men in one particular factory, however, might try it voluntarily as an experiment. This at any rate would supply us with experience for future guidance. On the other hand employers would probably raise objections on the score of expense and temporary suspension or dislocation of work. There are probably few employers who would object to an entrance medical examination of apprentices, also to the examination being repeated periodically during the years of apprenticeship, since physical or other defects might be detected, so that the youth, not yet too old, could be removed and given the opportunity of taking up other occupation. There is the feeling where a workman has passed through his apprenticeship and has undergone the periodical examinations that, even if after twenty years of service he is found to be the subject of heart disease, for example, he should be allowed to carry on, so long as the weekly returns of the factory show no signs of a decline in the man's output and no indications of failing health. The firm in the circumstances would of course accept the responsibility.

The health aspect of the periodical medical examinations also calls for consideration. Children commence factory work in this country at the age of 14 years; by the time they reach 18 they are spoken of as "young persons." There would be advantages to the youths themselves if, after completing their apprenticeship and having attained the age of 18 or 19 and they have decided to continue at a particular trade, they were medically examined and pronounced fit to remain in the employment. It may be that for the physical breakdown in health of many young persons during the past years the non-repetition of the medical examination of children after having been drafted into factory life has been to some extent responsible.

The early detection of disease or of some unfitting deformity would be helpful alike to the worker and to the employer. The examination might in the case of the older employees also show whether the individual was fit for the particular work, and whether the occupation was suiting him, for men and women cannot go on working for several years in succession without some structural changes occurring in the body as indicated by a rise of blood pressure or an impairment of the action of the heart which dietetic and medicinal treatment accompanied by a respite from work might possibly remove. It would be interesting to know whether the tendency for the blood pressure to rise is greater in male than in female workers, and whether in this country the morbidity rate between the ages of 15 and 50 is higher for women than for men, since this is stated to be the case in the United States of America. The blood pressure of operatives in our own country has been dealt with by a Governmental Committee,* and a table showing the findings obtained by Pembrey and his colleagues appears in Professor Collis's book *The Health of the Industrial Worker*. A comparison is made of the blood pressure of men employed in the tin-plate trade with that of men employed in metal-grinding. Taking the average blood pressure of men as 130 mm. Hg, I give briefly the average blood pressures of men in tin-plating:

Between the ages of 20 and 24	=	151 mm. Hg.
" " " 25 and 29	=	158 "
" " " 30 and 34	=	158 "
" " " 35 and 39	=	160 "

For corresponding age periods in metal-grinders the blood pressures are 143, 152, 159, and 155. In the weaving trade both men and women are employed: the work is carried on in a heated and humid atmosphere, and as a consequence blood pressures are considerably lower:

For females of 20 to 24	=	105; for males	=	127
For females of 25 to 29	=	100; for males	=	118
For males only 30 to 34	=	126
For males only 35 to 39	=	106

In weavers the blood pressure is generally speaking low, and in the first decade of working life it is lower in females than in males. The data are interesting, but in view of the American experience we require further information. In male workers engaged in tin-plating and metal-grinding the gradual rise of blood pressure is in keeping partly with the advance of age and the nature of the employment.

With these facts before us and the necessity of observing the physical changes which occur in men who have followed a trade for several years, can there be any serious objection to a medical examination of men on their taking up work for the first time in a factory and a record given and kept of the results of such an examination? The men would enter upon their industrial career with a fairly accurate knowledge of their own physical condition. There are some sections of the Labour party who might not approve of this, and yet there are certain trades at the present time in which a pre-occupation examination is already required. No men, for example, are allowed to undertake caisson work without submitting to such a medical examination, and such is required, too, of men who are applicants for railway appointments, for the police service, for work in white lead factories, and also in the gold mines. A medical examination should not be a deterrent but a guide to an applicant as to the particular kind of work he should undertake, and yet I must admit that, so far as the taking on of dotal labour at the factory gate is concerned, an experienced foreman is a better judge of an applicant's special fitness for the particular kind of work than a doctor can be. The foreman can at once spot the individual who is likely to do the work satisfactorily. A careful medical examiner, however, can be of assistance in occasionally detecting beneath the strong frame and the healthy appearance of the workman the existence of some serious disease, such as thoracic aneurysm or aortic regurgitation, which would unfit a man for labour involving heavy strain. Pulmonary tuberculosis also might be detected and the individual be given the opportunity of treatment. It might be objected that the medical examination, by preventing men taking up certain trades, would increase the number of the unemployed; but opposed to this would be the fact that only the fittest men

* Departmental Committee on Humidity and Ventilation in Cotton Weaving Sheds, Second Report, 1911.

would be recommended to take up the harder trades and the less physically fit sent to those which are less arduous. This may sound very well, but is it likely for one moment that labour would consent to such an assignment and distribution of applicants for work? Men are neither machines nor draught animals, nor is there the slightest reason why physical fitness should thus be penalized. Quite apart from physical fitness the personality of the worker must be considered, always remembering that his health is his capital.

I have suggested that there ought to be a re-examination of all young persons employed in factories at an age of 18 or 19—that is, after they have been working a few years. Shortly before the war I was struck by the large number of deaths of female workers between the ages of 18 and 25 which had been occurring in Germany, but on investigation I found that a similar event was taking place in this country, and at the present time it is occurring in the United States of America. It is generally held that girls develop more quickly than boys, but in the United States it has been found that a larger number of girls than boys are the subjects of serious malnutrition, the percentages being 6.5 for boys, and for girls 9.2; also that orthopaedic defects, such as curvature of the spine and other deformities, are more common among girls than boys. The high mortality rate of young female life alluded to a moment or two ago is not, as I have already indicated, confined to one country. In Vienna there was observed a rise in the mortality rate from tuberculosis in female workers between the ages of 15 and 20, believed to be the result of hard work, poor food, and factory environment. Young females working in the cotton mills of the United States are said to have a higher death rate from tuberculosis than those not similarly employed. Among the industrial policy holders of one large American society it was found that between the ages of 15 and 19 the rate of tuberculosis of the lungs among male wage-earners was 7.5 and the rate among females was 14.6 per cent. higher than the rates for the same period among the general population. The experience of the American authorities re the high rate of pulmonary tuberculosis among female workers in the cotton mills is not that of Dr. W. A. Daley, the medical officer for Blackburn.

It is none the less desirable, however, that during the early years of their employment in a factory young persons should be medically examined, for that this is a vulnerable period, particularly of female life, is shown by the tables of the Metropolitan Life Insurance Company of America during the last decade in the increase in the number of deaths of girls between 15 and 20 years of age, while other age periods show a decrease; also that while there has been an increase in the tuberculosis death rate amounting to 5 per cent. in adolescent girls, the mortality rate from the same cause in boys of the same age has decreased 25 per cent. There is no satisfactory explanation of this rise in the tuberculosis death rate in young women. The modern style of dress has been suggested as a cause of illness, but there is nothing to support this statement; nor can it be an aftermath of the war. Whether the physiological conditions in operation at this period of life have anything to do with it I am not prepared to say.

Should a medical examination of the workers during their factory career ever be established in this country, might then the health risks not, in some way or other, be brought within the range of life insurance so as to give to the examination an additional useful purpose? In a recent address delivered elsewhere I drew attention to "group life insurance," whereby a whole factory of workers could be insured at the rate of 6d. per head per week, so that in the event of the death of a worker from any cause the dependants of the deceased could receive £100. There are insurance companies in this country willing to take the risk. In the United States, where the scheme is in operation, it has diminished the labour turnover in the factories, and it has improved friendly relationships between employer and employed. In America it is run at the employer's expense, but there is no reason why it should not be made contributory. The Life Extension Institute of America* provides an annual health examination of its policy holders; it also arranges for a medical examination by its board of workers engaged in factories, also of persons employed in commerce. The idea is to detect disease in its earliest stages. The institute maintains

* The Survey, August 16th, 1921, *The Life Extension Institute*, by Michael M. Davis, Junr.

that by this means it has prolonged life and extended the period of a working man's career. Each member of the institute is carefully gone over, even to the extent of an x-ray examination, and treatment is arranged in co-operation with the member's own doctor, to whom a medical report is forwarded. At first private medical practitioners raised objections to the scheme, but the antipathy has gradually subsided. While the scheme combines "group life" and "group health" insurance, the men and the employers sharing the expenses equally, the management of the fund is entirely in the hands of a Mutual Aid Association of the employees. The medical reports go direct to the individual workers who have been examined, and are not seen by the employers, who therefore have no information of the physical fitness or of the health of the men which could be made an excuse for disqualifying them for work. Upwards of 200,000 examinations have been made by the Life Insurance Institute in ten years, during which many persons believed to be quite healthy were found to have physical defects or disease capable of cure or of being benefited. In women, for example, cancer in its early stages was detected and removed, with the result that many of the women are alive to-day.

As further illustrating the importance of periodical medical examination of the workers Dr. W. B. Fisk of Chicago gives the results of the examinations during 1921 of 3,676 employees, many of whom had been over thirty years in the service of his firm. Among the 3,676 examined 1913 defects were found, of which 768 were likely to cause loss of efficiency, and, of these, 471, or 11 per cent., were incurable. Notwithstanding these figures, defective employees are not, except under special circumstances, discharged by the firm. The men are given lighter work or they are pensioned. There is much to recommend the scheme; the subject is at any rate worthy of consideration at a friendly conference of employers and employed, and of medical men who are interested in industrial hygiene.

One of the greatest stimuli to industrial efficiency is work—regular work carried on under hygienic conditions; on the other hand, as causes of industrial inefficiency we cannot overlook individual slackness, prolonged unemployment, and frequent "strikes." The apparent light-heartedness with which strikes are sometimes entered upon, and to many of us the unconvincing excuses offered for the attitude assumed by the classes concerned, amaze many thoughtful persons among the community, who, looking impartially upon the varied aspects of labour problems, have serious misgivings as to the future prosperity of the country. This is not the place to discuss the legitimacy of strikes, but the growing disinclination in these days to fulfil obligations and to recognize the dignity of service is almost certain to bring its own Nemesis of unemployment and discontent. Apart from the physical suffering which strikes impose upon families, also the depressing effects upon the men who are incidentally involved, the longer the men are away from work the flabbier become their muscles, the softer their hands, and less the desire of the men to return to work. Prolonged strikes and unemployment are therefore serious causes of industrial inefficiency.

Time will not permit of me discussing the subjects of alcohol and work, also of food and efficiency, nor the relation of industrial inefficiency to fatigue. Welfare supervision and the rendering of "first aid" have done much to humanize industry. Roughly speaking, factory output is the result of the united effort of machinery and the person who guides it. There may be a thousand machines running at one and the same time in a particular factory, and the machinery is running the at varies, even in the same room, according to the individual behind it. In other words, although inanimate machinery is driven by regulated force, the work accomplished is largely influenced by the alertness of the individual who is superintending it. However much we may admire the beauty and mathematical precision with which a machine works, man is superior to the object which his intellect has designed and by which it has been given executive form. Always repeating the same process, the running of machinery becomes monotonous, and this monotony is reflected upon the individual who superintends it. Metal, we know, when overused is liable to exhibit something akin to fatigue, and as a consequence the output may be imperfect, but in the moving frame and rolling cylinder there is no sentience. Therein lies the difference between the human body and a factory machine, and an explanation of why the nervous system of the mill

worker breaks down under the regular running and persistent noise of machinery. The trend of human legislation is in the direction of the humanization of industry, of lightening burdens which are oppressive, and of removing dangers which threaten or destroy life. We are marching on, taking care meanwhile not to confuse sentiment in industry with the humanizing of it; for the two are not one and the same. There is much yet to be done, but in its desire to solve problems concerning industrial hygiene labour must co-operate with factory ownership, factory management, and medical inspection, for the problems cannot be settled by sentiment, but by reason and experience, and by an impartial consideration of all the circumstances involved.

DISCUSSION.

Dr. W. SALISBURY SMARKE said he was much interested in the table in Sir Thomas Oliver's paper which showed the differences in blood pressure and presumably of heart wear in different occupations. In connexion with railway work he had found differences in these respects in different grades, but his analysis was not yet complete enough to indicate whether physical type or occupation was the predominating factor. He hoped to be able to throw light upon this point and also upon the early signs of heart wear before the usually recognized signs of defect were apparent. He was referring to active and apparently healthy men and not to sick men.

Dr. ALEXANDER SCOTT said that the medical examination of workmen depended largely on the personality of the doctor. The examination was at first looked on with suspicion as a possible danger, tending to lower wages or otherwise to injure unfit or unsuitable workmen. By interesting the workmen in the examination and explaining the advantages of early recognition of conditions requiring to be remedied he had been able to establish a happy relationship between the workmen and himself, which allowed the examinations to be carried out under agreeable conditions.

Dr. G. E. ORME said that amongst the various factors tending to increase the sickness incidence and death rate in women mill workers as compared with men were (1) changed conditions of home life, lack of parental influence and control, and lack of early domestic education; and (2) increased consumption of alcohol, especially amongst young women.

Professor GLAISTER referred to the legal relationships of employment in which there was a contract of service, written or implied, between master and workman. The employer was entitled to expect from the employee "a fair day's work for a fair day's wage," these being mutually arranged. He was of opinion that the time had arrived for medical examination of workers following upon the examination of young persons, as required by the Factory Act, and in view of the responsibility incurred under the Workmen's Compensation Act. This examination could not, he thought, be legitimately objected to by the trade unions. He held the view that occupational mortalities were not quite of the value attributed to them, in respect that the personal equation of the individual workman was swamped in the slump. He considered that important factors in the fitness for work were the conditions of home life and the personal habits of employees. He thanked Sir Thomas Oliver for the views put forward, as they afforded important subjects for consideration.

Dr. JAMES R. KERR emphasized the importance of the physical efficiency of the worker in the general efficiency of the factory as estimated by output. The incidence of scoliosis to which Sir Thomas Oliver referred probably occurred in the young female workers as a direct physical result of neglect of recreative exercise in the presence of wrong postural tendencies. The benefit of facilities for recreation in connexion with factories should be better known, and the more artificial the nature of the occupation, and particularly if it involved asymmetrical use of trunk or limb muscles, the more essential it was to have adequate and experienced medical supervision of games, physical drill, and gymnasium exercises. As regards welfare work, he was glad that Sir Thomas Oliver laid down the serious warning that the greatest care must be taken not to confuse sentiment in industry with the humanizing of it. It was of primary importance that medical opinion should direct and guide all efforts and schemes for the welfare of

the factory worker. The medical examination of employees demanded the proper spirit and personality on the part of the doctor associated with frankness and fairness toward the employee in order to obtain the most beneficial results.

THE TREATMENT OF INDUSTRIAL ACCIDENTS

BY

JAMES R. KERR, C.B.E., CH.M.,

The Pilkington Special Hospital, St. Helens, Lancs.

FROM among the subjects which naturally fall to be discussed under the title of this paper I am forced by the exigencies of time to select only a few of the more fundamental.

In the first place, we have to bear in mind that the treatment of an industrial accident has very close interest for the many participants in its immediate and remote results; that, in fact, the victim of the accident and the attending surgeon are only the centre points round which circles of sentimental, financial, and economic interest are created. It is recognized that the appropriate setting for the entire picture can only be one in which complete harmony of purpose and mutual support exist among all those concerned.

I cannot refer here to the methods of accident prevention beyond the general statement that the first line of defence of the workman against himself and for the safety of his fellow workmen is the systematic medical examination of employees and in this connexion to record my experience that workmen readily appreciate that the opportunity of being examined at the factory does not turn out to be the disservice to them which at first sight they may have been encouraged to believe it would be.

In this country we have not written so much regarding the treatment of industrial accidents and the organization of factory medical service as has been done in America. No doubt the large plants that are set down and the mushroom growths of great industrial communities round new and probably somewhat hazardous manufacturing or engineering enterprises have made it more obvious to the employer that the provision of ambulance and hospital service must be reckoned in with the cost of production. No doubt also the very fact that these medical arrangements were started there *de novo*, not grafted on to pre-existing and probably inadequate arrangements as is the case in an older country, has given our colleagues in the United States a Factory Medical Service very inclusive in its efforts and housed in first-aid rooms and works hospitals which compel our admiration. On close examination, however, it would probably be found that in our densely populated coal-mining, iron, pottery, etc., areas the arrangements for the care of accident cases are of an unsuspectedly high standard. It falls to my lot to see a very large number of accident cases from a considerable portion of industrial England, and the feeling I have is that although there is good provision for the immediate and immediately subsequent treatment of accidental injuries of all kinds, there comes a stage in the progress of the case when there is no adequate provision for the next essential procedure towards the restoration of the patient to his working capacity. In this matter of subsequent treatment I feel that we are behind France and Germany.

To come back to my opening remarks, I would repeat that it is essential for us to appreciate the far-reaching consequences which result from an accident to an employee. The employer is concerned in the loss of the man's work and output, and the community has got to bear the burden of supporting a non-producing member. The amount of the compensation payment is of subordinate importance to the loss of the man's service as a workman, a skilled artisan—that is, "a producer," whatever his job may have been. The situation thus broadly outlined has been of late years squarely faced by employers, insurance companies, and friendly societies representing the workers. These various interests are agreed that, quite apart from its humanitarian and medical aspects, adequate attention to injured operatives is an economic proposition. The weight of opinion represented is so great that arrangements on the best lines are certain to be made on a wide scale at a relatively early date. The workmen of this country are sharply alive to the fact that during the war nothing, from the moment they were wounded, was spared in the endeavour to re-establish their fitness for service. They know what hospitals mean, and their appreciation of what orthopaedic surgery has done for them

and their comrades is ever present. When wounded in the industrial conflict these men will not accept with equanimity the compensation payment of 35s. a week with inadequate or haphazard after-treatment. Their desire will soon become a demand which in the last resort the State dare not disregard.

Organized hospital treatment of accidents and disablements, even should it not be above the level of that provided for the injured German worker, as seen by me in 1912, is bound to come. Confirmatory words are found in the report of the Departmental Committee appointed to inquire into the system of compensation for injuries to workmen (Part 5, Section 2), which also states that:

"The expenses of such extra services should be provided by the employers because the need for them has been created directly by the risks of employment, and they will have a material effect in reducing the amount of monetary compensation payable under the Act."

Having thus disposed of the question of the cost of treatment of industrial accidents I turn to the practical treatment of the injured workman. I must leave out of consideration meantime such factors contributing to accidents as monotony of employment; overtime; the shift factor; piece work; the illumination factor; and the risk factor involved in the particular occupation itself. The teaching of first-aid methods is taken up with such enthusiasm in this country, and so many laymen are efficient in this work, that treatment on the spot and conveyance to the dressing station, the works surgery, or the doctor's surgery, are well carried out.

In cases of "shock" the time which elapses between the accident and the induction of a morphine analgesia is of vital importance, especially in younger employees, and I think it well to have at each dressing station a supply of hypodermic doses of morphine ready for immediate injection. As a practical point I find the convenience and economy of the Tubanie outfit, which has the prepared solution ready to be expressed from the flexible capsule through the needle which is fixed to it, without any delay from a rusty needle, or a broken syringe, or an insoluble tablet, etc. These capsules can be kept in an envelope sealed and initialled by the works doctor, and are used only by him or under his orders.

The supply of cottage and other local hospitals throughout industrial areas is, as a rule, very good, and the surgical lessons from the war are reflected in the procedures adopted. I am

not aware, however, that the heated resuscitation chamber is sufficiently used. In every hospital liable to receive accidents some such provision should be made, and probably the most convenient is the electric quilt, which should be kept hot in readiness night and day, the resistance interposed between

the main supply being used as a heater for a two-pint container of a normal saline or a sodium bicarbonate solution.

The posture of burned, scalded, lacerated, or crushed limbs should be considered from the first with a view to the ultimate function, and it will be found much easier to place the affected limb in an orthopaedically correct position at once than to wait till later. As the patient is presumably under the influence of morphine there will be less pain on movement than on the following day. In view of the brilliant results of modern orthopaedic surgery, as tested out by the difficult and

numerous cases of the war, one can confidently plead for the most advanced conservatism in the treatment of injuries. On the other hand, to those who, on account of the circumstances of any case, are in perplexity as to whether they can just manage a Syme's amputation as the least mutilating result of an injury, I would say that a "below knee" is an amputation that readily lends itself to the application of a serviceable

artificial limb. It requires no special ankle fitting, and therefore no conspicuous boot, as does the artificial appliance for the Syme's amputation. Incisions for drainage, etc., must of course be kept away from the bearing surface of the head of the tibia, although even when these have been made they can be accommodated for in the design of the bucket.

We may pass to what is known as the *after-treatment*. Many of the cases require movements, active and passive, possibly massage and faradic stimulation, re-education of muscle, and graduated exercises. The rate of recovery is very satisfactory and the only difficulty which arises is that many doctors do not take advantage of the treatment at as early a date

as the condition of their patient would actually permit, and that time and opportunity are to some extent lost thereby. However, with the provision of the facilities one finds that the demand increases.

Most of the hospitals of this country owe their inception and continued existence to the anxiety of all thinking men to provide against the turn of Fortune's wheel. These excellent institutions

The Hall for Mechanotherapy (lower end). These special appliances are used for helping the movements of stiff joints and the development and re-education of injured muscles. All are finely poised and capable of delicate and gradual adjustments to suit the individual cases.

The Hall for Hydrotherapy: the Warm Pool. This pool, 36 ft. long by 20 ft. broad, contains warm water at 98° F., and is maintained in turbulent motion by great volumes of compressed air forced into it through orifices in long pipes lying at the sides. Patients are exercised in this water, while active movements of shoulder and hip is floating, supported by the water, and thus helped. This helps placed into the water, which is 3 ft. 6 in. deep, and

are trifles to the forethought and thrift of the worker and to the broad views of the employer. They provide an immediate haven for the sufferer. The history of these hospitals is a long and honourable one, but it is obvious that they can never supply the need for the specialized after-treatment—operative or by physiotherapy—which has been brought into great prominence and found to be of inestimable service during and since the war. The splendid recovery of our soldiers and sailors from crippling war wounds is well known, and the surgical experiences of the war have widened and advanced the range of restorative treatment. The variety and severity of factory accidents bear close comparison with those of modern warfare, and it has only to be mentioned to receive universal acquiescence that the benefits of the proven best treatments should be available for the victims of industrial injuries; and, what is more important, that there should be continuity of after-treatment and after-care. While surgeon to one of the large orthopaedic and limb-fitting centres I have simultaneously had the opportunity of applying to industrial accident cases the methods and resources of orthopaedic surgery, and for several years now we have been providing specialized treatment of the sort to which the Departmental Committee on Industrial Accidents refers. It is very satisfactory to be able to report to this Section that insurance companies, employers, the patients, and their doctors are most appreciative of this new phase of specialized surgical work.

It may be useful to consider the course of treatment followed in typical cases referred to me for after-treatment. The doctor referring the case, and probably also a doctor acting for the insurance company or the employers, provide reports which give preliminary information. The examination of the patient includes a detailed measurement of the range of movement of each joint, including of course metacarpophalangeal and interphalangeal joints, etc. The state of any nerve lesion, if present, is investigated. Stereoscopic x-ray photographs are taken, and frequently photographs and plaster casts, to serve as records for comparison later. In a certain number of cases the paralysis present is found to be due to want of proper posturing during the probably long period of previous treatment—for example, a case of fracture of the humerus presented itself with so marked a condition of drop-wrist that the musculospiral nerve was suspected. Appropriate splinting for three weeks resulted in some flicker of voluntary recovery, and further treatment completed the case. On the other hand, a fall of coal had severely excoriated the outer side of the upper arm but had crushed the tibia and fibula, fracturing them. The patient was up and walking about with a very serviceable leg before treatment was sought for the condition of drop-wrist which was manifest. In this case exposure of the musculospiral nerve discovered it to be adherent to the bone, ingrained with pieces of coal, and constricted in a dense fibrous tissue

mass. Surgical interference was essential before physiotherapy could be of any avail. The recovery then followed a normal and rapid course. Fractures at the elbow likewise present themselves with marked ulnar wasting, etc., on which no amount of massage would make any impression until the nerve lesion has been dealt with. It must therefore be understood that the function of an orthopaedic hospital is not "glorified rubbing." On the contrary, the orthopaedic hospital should be

Thermotherapy: Hot Dry Air Treatment. Here are shown patients with limbs being subjected to hot dry air (250° to 300° F.). The asbestos-lined cabinets which enclose the parts under treatment are supplied with compressed air which has passed through regulated electric heaters.

a centre, available to the doctors of a wide area, for reference in difficult and tedious cases, to treat which they have neither time nor adequate opportunity. Corrective osteotomy, arthroplasty, arthrodesis, tendon transplanting, and all the surgical devices to restore limbs to usefulness must be in the armamentarium. It is obvious, therefore, that the after-treatment of industrial accidents covers a wide field in operative procedures, quite apart from the physiotherapy measures.

In contrast, one has the type of case in which fibrous tissue, the result of prolonged and profound sepsis, holds the limb or the hand in an unyielding grasp. In view of length of time it may be that shrinkage of joint

capsules, ligamentous structures, etc., demand certain preliminary operations, and all manner of devices for overcoming contractures or adaptive shortenings. The end-results in such cases after prolonged and intensive physiotherapy treatment have surprised most competent observers.

Having thus examined the patient and carried out such preliminary treatment as I have just suggested where required, we shall follow him through his physiotherapy course.

[Dr. Kerr here gave a description of the physiotherapy treatment rooms and equipment at the Pilkington Special Hospital, St. Helens, probably the largest installation in this country, and showed photographs illustrating the warm pools, the multiple baths for arms and legs, the hot-air cabinets, the electro-room, the mechanotherapy room, plaster casts, etc.]

Should we seek for adjectives to characterize the details of modern orthopaedic treatment we might without offence speak of the methods as purposive, co-operative, insistent, intensive, cumulative, and of the results not merely as full of promise but even now justifying beyond cavil the adoption

of the title "Orthopaedic" by hospitals of the type I have had the pleasure to describe to you.

In conclusion, the efficient treatment of industrial accidents is of vital importance to the community and to the State. The figures showing the loss in man-power and in wages and the concomitant burden on industry are at present enormous. The employer, I assert, is willing and anxious to co-operate with you because the great factor of industrial success lies in the efficiency of the worker, which means maximum output, and is well aware that scientific and controlled experiments have proved that it pays handsomely to cultivate the physiological best in the employee. The larger insurance companies also now realize

The Hydro Room: Multiple Baths for Arms and Legs. In foreground and to right are sets of baths for leg cases. Behind are multiple, "waterfall" baths for arms. Four are in action. "Contrast" foot baths are shown.

that the victim of an industrial accident is not profitably reckoned as merely a "claim" to be badgered and harassed into what is called a "settlement" by a slow process of starving out. A long and intimate acquaintance with injured workmen discloses to me that a disabled employee makes an excellent and appreciative patient. But you must not talk medical nonsense to him. Explain briefly and plainly what the situation is, and do not minimize the severity of the injury or the length of time required for recovery to be gained. From the moment of his injury he has before him a vision of the future of his dependants, and it is our privilege to give the utmost of our skill and ingenuity to his and their service. I am fortunate in having a hospital, probably pioneer, devoted to the treatment of all sorts of crippling—children and adults—but chiefly crippling resulting from industrial accidents. The acquired orthopaedic experience of our staff is now concentrated on civil problems, and the great value of the service is widely recognized by those who have the treatment of industrial accidents in their minds as one important factor towards the success of our industries in international competition.

DISCUSSION.

Dr. JOHN C. McVAIL said that what impressed him in Dr. Kerr's interesting paper was the illustration it provided of the influence of Government policy on the prevention and treatment of industrial accidents and disease. The increase of the employer's financial responsibilities through the superimposing on common law of the Employer's Liability Act and then of the successive compensation Acts had been accompanied by a tremendous advance in the control, by means of orthopaedic surgery and otherwise, exercised over such accidents and diseases, in the direction both of prevention and of cure. Dr. Kerr's paper was an admirable exposition of the good work that was being done.

Dr. W. SALISBURY SHARPE said that cases frequently came under notice in which compensation was demanded for incapacity, the extent and duration of which was due to bad treatment and not to the initial injury, the employer being made responsible for the effects of treatment over which he had no control. He would like to know how the special hospital which Dr. Kerr represented was supported.

Dr. A. COLES said that much loss of time was due to a trivial injury becoming serious by neglect. If, instead of washing a wound immediately it happened, it was painted with iodine, much septicaemia would be avoided. If a system of partial employment for the partially disabled was encouraged, the injured person would return to work at an earlier date, to the mutual advantage of employed and employer.

Dr. KERR, in reply, agreed with Dr. McVail that a great advance in the treatment of injured workmen had been achieved by placing responsibilities on the employers. He considered it important that the first dressing applied to a wound should be a sterile one. He explained that the Pilkington Special Hospital specialized in the after-treatment of industrial accidents, and that cases were admitted on a simple payment basis, which had proved acceptable to insurance companies, employers, and private patients.

APPARATUS FOR THE ESTIMATION OF THE WORKING CAPACITY OF AN UPPER EXTREMITY.

BY

JOHN GLAISTER, JUNR., M.B., CH.B. GLAS.,

Senior Assistant to the Professor of Medical Jurisprudence, University of Glasgow.

THE civil aspect of medico-legal practice presents many difficulties, more especially that branch of this specialty which deals with the perplexities of the medical aspect of the Workmen's Compensation Act. For the purposes of awarding compensation one is frequently called upon to examine individuals who have sustained injuries to an upper extremity, and to express an opinion as to their capacity for work. In the past few years from the many cases coming under my observation in this respect there have been a considerable number who have during examination given the impression of unwillingness to demonstrate

their capacity for work. After careful scrutiny and consideration of the existing tests, I came to the conclusion that perhaps the quality and character of these tests were partly to blame on account of their inaccuracy and difficulty of application.

We may now consider for a moment a method commonly employed for estimating the working capacity of the upper extremity as a whole by means of weights. The examinee is usually requested to lift weights of different sizes, and the amounts of the weights lifted are carefully noted by the examiner. Assume for the moment that the patient is a willing one, there is a strong objection to this test as described, inasmuch as it does not permit of estimating the work done by the extremity of the individual. To state that a man is able to lift a weight of 28 lb. without complaint of pain or discomfort is of course stating a useful fact in relation to the power of the extremity, but it would have much greater import if stated in terms of work actually done, which can be satisfactorily expressed in foot-pounds, because it is with the working capacity that we are chiefly concerned. Another strong objection which is apparent is that in the case of the non-co-operative patient—and there are many—he appreciates the size of the weight, and if he is astute, which is not uncommon in this class of case, he may easily read the amount of the weight engraved upon it. These factors frequently undermine any little moral courage a man may have to attempt to lift.

After careful observation of the cases so tested by me and by others, I endeavoured to overcome these objections by having a suitable and simple apparatus constructed. This construction was carried out for me by the local branch of the Surgical Manufacturing Company, Mortimer Street, London. My aims of this apparatus were:

1. To have the weight lifting test recorded more or less automatically in terms of foot-pounds of work done by an extremity.
2. To obviate the objections already mentioned.
3. To check attempts at malingering.
4. To record uniform results.

I have arranged for this apparatus to be before you to-day, so that it can be demonstrated. For purposes of description it might be more or less accurately described as a box having the following dimensions: length 36 inches; breadth 12 inches; depth 20 inches.

It should be noted that you see this cabinet in its experimental stage with its accompanying crudeness, as many changes have been effected in its structure since it made its first appearance. On one side there are two sliding doors fitted, having such dimensions that when opened ready access to the interior is obtainable. On the upper surface of the cabinet are six holes or apertures, supplied with metal collars, through which pass six steel rods to the inside of the apparatus. At the uppermost portion of the rods is fitted a short, comfortable steel handle, which has been acetylene welded to the rod ring. This ring is formed by the upper portion of the rod itself being curved, and its object is to accommodate a finger in order to add additional security to the hand grip. The lowermost portion of the rod is hook-shaped, for the purpose of suspending the weights. Each rod measures exactly twelve inches from the base of the finger ring to the commencement of the hook. It should be noted that the finger ring can be utilized to allow the fingers to operate on the weights individually if so required for a purpose to be considered later. The rods are made of steel which has been semi-tempered in order to permit of suspending a 56 lb. weight without straining them. At the base of the finger ring a rubber washer will be noted; the object of its presence is to eliminate noise during the operation of the weights. The weights suspended are ordinary standard weights, weighing from 1 lb. to 56 lb. Weights from 1 oz. to 1 lb. have also been supplied for testing the power of the individual fingers, and for the re-toning of the intrinsic muscles of the hand. Each of the larger weights is fitted with a U-piece which is welded on to the bar of the weight; this measure prevents the hook slipping from side to side when the weight is being lifted.

The following merits are claimed for this piece of apparatus, as the results of using it for a considerable period in many cases:

1. The examinee is unable to observe the weight he is lifting; in many instances it would appear doubtful if he realizes that he is lifting an ordinary weight at all. I have been frequently

asked whether the gripping of the "black handle will give a shock."

2. Any standard weight can be fitted to the machine.

3. The order of the weights can be altered practically *ad infinitum*, thereby preventing a man becoming familiar with the order of the weights at a subsequent examination.

4. When volition is present it is foolproof against malingering.

5. The results are constant.

Each time an individual fully raises a handle with a weight suspended he performs an accurate amount of work—that is, the number of pounds raised is expressed as foot-pounds of work done, as each pound is lifted through the space of one foot.

The apparatus is applied in the following way: The examinee is requested to lift a certain handle as often as he can on which is suspended the heaviest weight which he has proved capable of lifting. The number of times the weight is fully lifted multiplied by the weight lifted gives the total work done by that upper extremity expressed in foot-pounds.

In cases of suspected malingering the test should be applied as follows: Test the claimant's ability to lift the various handles. Assume, for the purpose of example, that the man states that he is unable to lift a handle on which a 1 lb. weight is suspended; ask him to lift an ordinary 1 lb. weight from the floor; if he does so readily and without complaint of pain or discomfort malingering can be strongly suspected. In a case of this kind the best procedure is merely to open the sliding door of the cabinet and show him the 1 lb. weight which he alleged he was unable to lift. In certain circumstances it may be found excellent to make a note of the fact and not demonstrate this act of deceit to the man.

An alternative method of detecting malingering is to place two or more of the same weights in the cabinet at the same time. The man may easily raise one of these and fail to raise a duplicate one when its turn comes.

In conclusion it should be mentioned that, judging from practical results, it would appear that the apparatus should prove extremely useful for exercises which have for their object the retoning of the intrinsic muscles of the hand or the muscles of the upper extremity following injury.

In cases where men will not attempt to operate the apparatus the examiner must of course rely on the objective signs of injury and its sequelae in conjunction with the general attitude of the man, and form an approximate opinion of the efficiency of the hand for work.

THE OCCUPATION DERMATOSES OF THE PARAFFIN WORKERS OF THE SCOTTISH SHALE OIL INDUSTRY.

BY

ALEXANDER SCOTT, M.B., C.M.,

Broxburn, West Lothian.

The skin lesions due to contact with oily paraffin in a crude or semi-refined state may be described as conforming to the following types, of which one only or several may be found on the same individual:

1. Occupation comedones.
2. Folliculitis and follicular dermatitis.
3. Dermatitis pustular.
4. Dermatitis papulare (erythema papulare).
5. Erythema simplex.
6. Dermatitis erythematosa.
7. Epithelioma (paraffin workers' cancer).

These, which include all forms of occupational eruptions met with in the Scottish shale oil industry, will be described under their various heads.

1. Occupation Comedones.

Comedones occur in parts exposed to contact with paraffin products, especially over the flexures of elbows, posterior aspects of elbows, upper aspects of shoulder-joints, and occasionally over knees. Their origin is purely mechanical, being due to obstruction of the sebaceous ducts with semi-solid paraffin substances, or to thickening of the superficial layers of the epidermis, causing obstruction of ducts. They are larger than comedones met with under ordinary conditions, more closely packed together, and confined to circumscribed areas, being most prevalent on the anterior aspects of the body and limbs. The outer layers

are pigmented and hardened. The comedones are easily expressed, but if left unattended are apt to be followed by the development of sebaceous concretions of a cystic nature, which are most commonly found over the flexures of the elbows. There is not the same tendency to acne formation as under ordinary circumstances, possibly owing to the fact that the materials obstructing the ducts are sterile and practically antiseptic, and it is only after they have persisted for lengthened periods that any tendency towards acne formation is seen.

2. Folliculitis: Perifolliculitis: Follicular Dermatitis.

Folliculitis consists of destruction of the hairs and hair follicles as the result of a mild inflammatory reaction set up by the action of shale oils. The follicles become somewhat dilated and are filled with epithelial debris and dirt, so that they appear as closely grouped clusters of black points over the parts affected. Occasionally a slight perifolliculitis occurs, in which the inflammatory condition extends to the surrounding skin, which becomes slightly raised above the rest of the skin tissue, and which ultimately becomes somewhat indurated and thickened. The most common sites are the backs of fingers and hands, and to a less degree on the forearms, the legs around the ankles, and the dorsal aspects of toes and feet; especially on the line of the extensor tendons of toes. There is never any tendency towards suppuration or sloughing, the condition persisting as described indefinitely. The usual appearance of dryness of the hands, with clusters of black points on backs of fingers and hands, is very characteristic among paraffin workers.

3. Dermatitis Pustular.

Two types have been observed:

(a) One in which the condition is characterized by the appearance of numerous small pustules over the anterior aspect of the body and limbs, and

(b) One in which the pustular eruption is due to the breaking down of the typical papule, which is the most prevalent form of occupational eruption.

(a) *Primary Dermatitis Pustular.*—A widely distributed pustular dermatitis has been noted among youths beginning work in the paraffin departments. This condition appears to be due to contact with semi-refined oily paraffin, which sets up an acute irritation of superficial layers of epidermis with pus formation. The channel of entrance appears to be by the hair follicles, as generally a hair is found in the centre of each pustule. It is most probable that there is an idiosyncrasy towards the action of paraffin in some of its forms, causing one individual to be acutely affected while by far the larger proportion escapes. Pustular dermatitis readily disappears on removing the individual from his particular form of work or on taking precautions as regards cleanliness. The tops of the pustules dry and are shed as crusts, without further return.

(b) *Papulo-Pustule.*—These occur as small pustular elevations on the sites of papules, the suppuration taking place at the apical part of the papule. As a rule these are not numerous, and are usually seen in conjunction with a papular eruption. They are not surrounded by an inflammatory areola, and are due to the breaking down of papules, either from a staphylococcal or streptococcal infection, or to the separation of a small necrotic area from the centre of the papule, after which the papulo-pustule disappears.

4. Papular Dermatitis (Erythema Papulare).

This is by far the most common type of skin lesion met with among the paraffin workers of the Scottish shale oil industry, between 40 and 50 per cent. of the workers being affected. The papules are known in the trade as "paraffin plukes," and are most typical of an occupation condition both in history and distribution.

Papular dermatitis consists of an eruption of small rounded elevations of a reddish colour, varying in size from that of a small peppercorn to that of a small pea. They correspond in every way to the typical primary lesion described as a papule, being solid, superficial, rounded in shape, and containing no fluid. As a rule the tops are convex, but occasionally there is apparent a minute central depression, from which a tiny thread-like core can be expressed or removed, and which corresponds to a necrotic hair follicle or sweat duct. I have seen in a very few instances small, soft papules with tiny horny excrescences

on top, giving the appearance of diminutive cutaneous horns, such being situated on the serotum.

The entrance of irritant to the superficial layers of the skin appears to be most commonly through the sweat ducts, but very frequently the hair follicles are involved, in which case they occupy the central position in a papule. There is as a rule no inflammatory areola around the typical papule. The papular eruption differs from other lichenoid eruptions, in that there is no itching or irritation, the papules do not tend to coalesce, and as a rule heal spontaneously. It has been frequently noted during the routine examinations of the workmen that the sites of papules vary from time to time, and that between the examinations some have healed and others have appeared in different situations. The papules may be present singly, or in twos or threes or in larger numbers until there may be a diffuse eruption of discrete papules. Between 40 and 50 per cent. of the workmen are affected with this type of eruption, and of those affected approximately 50 per cent. show not more than three or four papules, 45 per cent. have a limited extent of eruption confined to a small area, and 5 per cent. have a diffuse eruption.

The distribution of the papular eruption is very typical. In the great majority of cases it is confined to the forearms, and as a rule is most pronounced over the ulnar aspect, though it is also prevalent over the anterior and posterior aspects, around the wrists and on the backs of the hands. Less frequently a few papules are present on the shoulders, legs, and dorsal aspects of the feet. In old-standing cases they are seen over the lower thirds of the arms and around the elbow-joints, and occasionally on the anterior aspects of the body, thighs, and on the face and neck. The palms of the hands and soles of the feet are never affected. Approximately 75 per cent. of those affected have eruption on the hands and arms only, 20 per cent. have both arms and legs affected, and about 5 per cent. have some eruption on the body, as well as on the arms or legs. The most typical position in which the papular eruption is found is over the ulnar aspect of the forearms, this being the part most in contact with the paraffin in its semi-refined state. On two occasions I have seen papules on the serotum.

The earliest appearance of papules after men begin work in paraffin sheds occurs in from ten to twelve days, and they may persist throughout the duration of employment. They disappear a few weeks after ceasing work among the semi-refined paraffin. Occasionally in old-standing cases the papules instead of healing assume a warty appearance, due to proliferation of superficial layers of epidermis, and to growth of connective tissue cells, forming scaly warts, at first soft, but gradually becoming harder and more indurated, with a covering of dry scales which are readily detached. This warty appearance is of a permanent nature. In the most chronic types of this condition of warty papule there is occasionally a tendency to increase in size, accompanied by the formation of a central necrotic area, which may separate and be followed ultimately by the disappearance of the warty growth, with atrophy of the skin tissue and the formation of a scar. These more chronic types are as a rule associated with an old-standing induration of skin, due to chronic erythematous dermatitis. As a still more advanced stage of the condition described the warty papule, instead of disappearing, grows until it assumes the characters of an epitheliomatous growth, with the usual clinical and pathological features of that condition.

5. *Erythema Simplex.*

This consists of a mild hyperaemia, in which the redness is distributed uniformly over the parts affected. The first appearance is a slight blush, followed by a greater degree of redness, which in the early stages disappears on pressure, to reappear when pressure is withdrawn. This hyperaemia is almost always limited to the forearms, which show a generalized redness, there being no "patchiness" in its appearance. In exceptional instances a slight degree has been seen on the feet. Associated with the increase in colour is a marked dryness of the skin. In the later stages there is a tendency for the erythema to become slightly purplish and to remain on pressure, the pigmentation of the skin being permanent. This condition may persist for years without alteration. In addition, there is a scalliness of the arms, in which the superficial cells of epidermis are readily rubbed off in fine scales. There is frequently seen a shiny or lustrous condition of skin, giving the arms a polished

appearance. There is never at any time any tendency to moistness or exudation, and seldom are there any subjective symptoms, such as itching or irritation, along with the erythema. This type of lesion frequently exists alone without the presence of other form of occupation eruption, and is somewhat prevalent among the paraffin workers.

6. *Dermatitis Erythematosa.*

This is essentially a dermatitis venenata of a subacute or chronic type, due to the irritant action of semi-refined paraffin on the tissues of the skin prolonged over a lengthened period for years in practically every instance. It represents a further extension of erythema, in which the congestion gradually merges into a chronic inflammation of the various layers of the epidermis and cutis vera, followed by induration, and, in the most advanced stages, by partial or complete destruction of small areas of the skin in the affected parts.

In the first stages, the lesion consists of dull red erythematous patches distributed irregularly over the anterior aspects of forearms, either broadly linear or roughly circular in shape, giving a honeycombed appearance to the skin. They are slightly raised above the surface of the skin, are very dry, and somewhat scaly. At first the condition is limited to small areas, but, as it becomes more old-standing, involves larger areas, the whole surface of the forearms being frequently affected. Associated with this erythematous condition there is usually pigmentation occurring in small patches over the parts involved. The erythematous stage may persist for long periods without further change, or healing may take place, the redness disappearing being replaced by some induration of the superficial layers of the skin, with a characteristic dry scalliness which is practically permanent.

Frequently the erythematous dermatitis progresses so that the deeper layers of the skin are infiltrated, and as the inflammatory process subsides small patches of atrophied skin, white in colour, appear, or there may be scar formation according to the depth of the inflammatory changes. There is frequently a tendency to the formation of small flay scaly warts, usually oval or circular in shape. In advanced cases the whole surface of the forearm appears indurated, hard, and thickened, giving a tanned leathery appearance. These warts, if injured by abrasion or mechanical damage, are apt to become irritated and undergo excessive epithelial proliferation, with subsequent growth in size.

The advanced condition of dermatitis may persist for many years or for a lifetime, with permanent roughness and wartiness of skin and a chronic desquamative process going on. The tendency towards the formation of warts may persist long after workmen have ceased to work in paraffin departments and have not been further exposed to causes of irritation.

Chronic dermatitis as described above usually coexists with old-standing papular dermatitis, in which the papules are of the indurated type, being hard and scaly. Thus in an advanced stage the forearms show pigmented patches, small white areas of atrophied skin, scars, scaly warts, and indurated papules.

The distribution of erythematous dermatitis is confined solely to parts in contact with paraffin substances. The forearms principally are affected, either in parts (especially over ulnar aspects) or generally. In advanced cases, the lower thirds or halves of the arms are usually also affected. Occasionally the dorsa of the feet show the condition to a slight degree, but there has not been seen the same amount of induration, the feet being better protected. The palms of the hands may show a slight tendency towards exfoliation of the epidermis, which becomes thickened and fissured as a result of the dermatitis.

The erythematous dermatitis of paraffin workers differs from others forms of dermatitis venenata in that there is never any tendency towards moistness of surface. There is never vesiculation or any formation of bullae, the general tendency being to assume a chronic course, and induration is of frequent occurrence. Dryness of the affected parts is the feature of paraffin workers' dermatitis, but an occasional slight excoriation of scar tissue, from injury or climatic conditions, may be seen. While a considerable proportion of the older workmen show evidence of healed or old-standing dermatitis, the condition has become less evident in recent years, and is practically confined to those who have been paraffin workers for years, the recent employees being free from this type of skin lesion.

7. *Epithelioma (Paraffin Workers' Cancer).*

Epithelioma as seen among the paraffin workers of the Scottish oil industry occurs in workmen about or over middle life who have been paraffin workers for long periods. It usually arises from the scaly warts which form as a result of the chronic dermatitis already described, or from an old papule, especially of the indurated type. The warts or papules giving rise to this lesion have as a general rule existed for a number of years in a benign form, until the epithelial covering begins to proliferate more rapidly, with increasing growth of the primary lesion, until the characters of malignancy develop. In the early stages of the degeneration the naked-eye appearances vary according to the primary condition, so a short outline of the development from a wart and a papule may conveniently be described.

(a) *Arising from Scaly Wart.*—In the benign condition the wart is somewhat oval or circular, about the size of a sixpence. It is covered by small scales which are readily removable, leaving a somewhat indurated base. The wart does not protrude to any extent above the level of the surrounding epidermis. As the epithelium undergoes proliferation, the wart increases in area and also becomes more raised above the level of the surrounding skin, until it gradually assumes the size of half a crown in area, raised about a quarter of an inch or more above the surface, and covered with thick horny scales. On reaching this size there is a tendency for the formation of fissures, or abrasions of the surface, from which a serous fluid exudes, causing crusting of the surface. The crusts are readily removed by any slight injury, but re-form. This appearance persists for some months, the area gradually increasing until the incrustation and warty covering of the growth eventually slough and disappear, leaving a superficial ulcer, from which sero-sanguineous fluid exudes. Subsequent growth of the ulcer in depth and size takes place slowly.

(b) *Arising from a Papule.*—An indurated papule has been already described as occurring in old-standing erythematous dermatitis. The papule as a rule persists in this benign form for many years. A central necrotic area may form, accompanied by the gradual growth of the primary lesion. After separation of the slough it may grow until it assumes much larger proportions than formerly, the growth having a central ulcer, surrounded by indurated edges. The growth of the ulcer extends peripherally and also in depth, the edges being indurated and undermined, until all trace of elevation of tissue above the level of the surrounding skin disappears, so that a large open ulcer is formed, with a base of red, angry-looking granulation tissue, bleeding profusely on the slightest touch.

When the growth is situated on the scrotum there is, as a rule, in the ulcerative stages, an overgrowth of epithelial tissue forming large masses, protruding above the surrounding surface, giving the appearance of a cauliflower excrescence, and, being very vascular, they bleed profusely. Ultimately the lymphatic glands are involved in this excrescence, so that in the latest stages the whole inguinal region is invaded by a large ulcerating cauliflower-like mass. The malignancy for a long time is not great as the lymphatic glands do not become involved till a late stage, but this varies according to the situation, the glands being involved earlier when the lesion is situated on the scrotum than when the site is on the arm or forearm. The most common situation is on the back of the hand or on the lower third of the forearm, but it also occurs on the scrotum, and it has been seen on the face, and at the outer and inner angles of the eyelids, in which latter case the features of a rodent ulcer may be assumed.

Epitheliomata also occur among retortmen, labourers, and stillmen. In these men the epitheliomatous growth does not arise from a previously existing condition due to the action of paraffin, such as a papule or wart as already described, but generally begins as a reddish pea-shaped nodule, in which the typical "cell-nests" are present practically from the onset, or on the site of an ordinary simple papillomatous wart or mole, or small cyst. There is the usual epithelial proliferation, accompanied later by the degenerative changes associated with an epitheliomatous growth. The epitheliomata which occur in oil workers and labourers, as distinguished from paraffin workers, without any primary condition of dermatitis, are as a rule found among those men—such as retortmen, labourers, stillmen, oil workers, etc.—who come into contact with ash, coke, or other gritty material. The scrotum is most frequently the site of such lesions, this being due to the difficulty of ensuring cleanliness of this region.

I have made a list of all cases of paraffin epithelioma which have occurred since 1900. In all 65 cases have occurred, of which 19 have been in paraffin workers proper, and 46 among the other grades of labour employed, such as retortmen, labourers, etc.

In the oil works comprised under Scottish Oils, Limited, there have been employed approximately five thousand workmen annually for many years, which number includes all forms of labour necessary in the distillation of oil shale and the refining of its products. It will be thus seen that the cancer incidence is approximately $1\frac{1}{2}$ per cent. in twenty-two years, or under 0.1 per cent. per annum. Nineteen of these cases have occurred among those definitely known to have been employed in green sheds (paraffin sheds or crude paraffin departments), there being approximately two hundred men thus employed annually by Scottish Oils, Limited, during those years. The incidence of this condition among these workers is thus 0.5 per cent. per annum approximately. The ages of the cases recorded vary from 37 to 79 years.

Three were under 40 years of age.

Thirteen were between 41 and 50 years.

Twenty-six were between 51 and 60 years.

Sixteen were between 61 and 70 years.

Ten were between 71 and 79 years.

The sites of the epitheliomatous lesions were:

Scrotum	21 = 47.7%
Arm, forearm, and hands	31 = 32.3%
Face	4 = 6.0%
Ear	3 = 4.0%
Nose	2 = 3.0%
Groin	1 = 1.6%
Lip	1 = 1.6%
Anus	1 = 1.6%
Leg	1 = 1.6%

Of the nineteen cases among paraffin shed men the lesions were most prevalent on the arms, forearms, and hands thus:

Hands, forearms, and arms	12 = 63%
Face, neck, and ear	3 = 16%
Scrotum	3 = 16%
Groin	1 = 5%

These figures are in accordance with the facts stated that among oil workers, retortmen, and labourers the tendency is for the primary lesion to occur on the scrotum, being malignant practically from its early stages, while among paraffin shed workmen, as a general rule, the lesion occurs as a degenerative stage of warts or papules, which are most commonly situated on the forearms.

ETIOLOGY: EXCITING CAUSE.

Paraffin Scale.—It has hitherto been believed that the scale itself was the cause of the dermatitis (H.M. Factory Department Reports, 1913), but recent experiments with animals have clearly shown that the actual cause is the oil, before and after separation of the scale, and that the scale itself is not the cause of the dermatitis. While the exciting cause has been found to be the oils, the actual constituent of those responsible has not yet been determined. Various theories have been advanced, but so far no one has been definitely substantiated with any degree of certainty.

1. *That Nitrogenous Compounds may be the Exciting Cause.*¹—In criticism of H. C. Ross's paper it may briefly be stated that all nitrogenous compounds are eliminated during the process of manufacture of the various final products, so that nitrogenous compounds as a cause of paraffin dermatoses may practically be dismissed from further consideration.

2. *Arsenic as a Cause of Paraffin Dermatoses.*²—As far as the paraffin workers of this industry are involved it may be said that arsenic is found in the raw material, oil shale, but only to an infinitesimal extent. It is also true that the dermatoses have some similarity to arsenic conditions, but nevertheless it can be said with certainty that the paraffin workers' dermatoses are not due to arsenical poisoning. On analysis of an average sample of oil shale it has been found that arsenic is present to the extent of 0.00056 per cent. by weight, or 0.0392 grain per lb., and that in the blue oil, which the workmen handle, it is present

¹H. C. Ross, in paper on occupational cancer, *Journal of Clinical Research*, vol. iii, No. 4, October, 1918, p. 321.

²Dr. Bayet, of Brussels—*Comptes Rendus Académie des Sciences*, Paris, 1919, vol. cxviii, pp. 701-706.

to the extent of 0.000015 per cent. As the process of manufacture of the finished products of shale involves repeated distillations, and frequent treatment with acid and soda, it is certain that any arsenic, if present, is eliminated, and, on the other hand, no skin eruptions occur in the crude oil department, in which they might be expected to appear, if due to arsenic intoxication.

3. *Light in the Form of Radio-active Substances as Cause of Paraffin Dermatoses.*—The influence of light and actinic rays is well known as the cause of epidermic hyperplasia. In the tropics conditions known as solar keratoses are found, due to the heat and high actinic power of the sun's rays. It is improbable that a radio-active substance is the determining factor in the causation of the various forms of paraffin dermatoses described, as these would be much more widely distributed, and it might be expected that many of those coming into contact with the various grades of oil, refined wax, burning oils, and other final products would also be affected, all these products being hydrocarbons from a common source.

Organic Sulphur Compounds as a Probable Cause.—The presence of sulphur, in the form of organic sulphides, is constant in oil shale, in the crude and semi-refined products, and to some extent in the finished products as well. These exist as thioalcohols or mercaptans, and are present throughout the different processes of distillation and treatment of the intermediate products. Similar types of lesions are found among tar workers, these also being engaged in distillation of hydrocarbons, with a considerable proportion of sulphur impurities. The possibility of sulphur as a cause of paraffin dermatoses must therefore not be overlooked.

The position may be summarized thus: The various forms of dermatitis, whether papular, pustular, or erythematous, found among paraffin workers are due to direct contact with some chemical substance which, by the formation of warts and indurated growths, acts as a predisposing cause of epithelioma, and that the determining factor or exciting cause of epitheliomatous degeneration is, in common with all other forms of cancer, unknown.

Predisposing Causes.

Age.—The influence of age is slight as a predisposing cause of papular or erythematous eruptions. On the other hand, it has a decided influence on the occurrence of epitheliomatous lesions, these practically never being got on men under 40 years of age, and as a rule these appear at more advanced ages than this.

Length of Service in Paraffin Departments.—Length of service is of considerable importance in determining the nature of the skin lesions. As previously stated, the primary form of pustular dermatitis appears after a few weeks' work in the paraffin sheds. The papular types likewise appear after a few weeks' service in these departments. The presence and degree of erythematous dermatitis are in proportion to the length of service. The less extensive and less indurated conditions begin to appear after seven or eight years, while the more indurated and more chronic types are only seen on men who have completed many years of service, the worst cases having been continuously thus employed for terms varying from twenty to forty years. Epitheliomatous conditions are only found after long terms of service, these usually arising from chronic warts or papules, which may exist in a benign state for many years before undergoing epitheliomatous changes. Those affected during recent years have been paraffin workers for periods from thirty to forty years.

Idiosyncrasy and Predisposition.—Accumulated evidence tends to show that some workmen have a greater tendency to be affected than others, the working conditions otherwise being the same. It has already been suggested that there may be an idiosyncrasy on the part of a few youths towards the action of semi-refined oils, by their having pustular eruptions soon after beginning work, while the majority escape. Likewise the fact that only approximately half of those working among the same materials and under the same working conditions suffer has never been otherwise explained, and the only reason that can be advanced is that there is greater tolerance on the part of some than of others. I have had occasionally under observation large warty growths with central necrosis, and suggestive of the stage immediately preceding malignancy, which instead of undergoing epitheliomatous degeneration have healed after separation of necrosed area. Cases such as those might be considered as only lacking in the personal factor, which must

have a certain amount of influence in determining the development of a benign into a malignant condition. These facts are suggestive that an idiosyncrasy may exist towards the action of paraffin substances, and that the personal element is a factor of some importance in the further development of warts and papules into epitheliomata. The following table shows clearly the proportion of those unaffected at four recent examinations since 1919:

	Green Shed Men (Crude Dept.)	White Shed Men (Refining Dept.)	Green and White Shed Men.
February, 1919 ...	28.7%	71.2%	42.0%
August, 1919 ...	29.5%	83.0%	44.5%
March, 1921 ...	25.4%	94.3%	49.3%
August, 1921 ...	39.1%	91.4%	47.5%

It will therefore be seen that a considerable proportion of men escape, many of whom have been paraffin workers for long periods. On the other hand, a number of those having eruptions have been paraffin workers for short periods only.

Want of Cleanliness.—In recent years very considerable attention has been paid to the importance of cleanliness, and facilities have been freely given for this purpose, as will be described later. Notwithstanding strict attention in this respect it cannot be said that the incidence of early or papular eruptions has been more than slightly diminished, but, on the other hand, there has been a marked diminution in the frequency of the more chronic types, such as erythematous dermatitis—so much so, that recent erythematous dermatitis is now uncommon, while the more chronic and old-standing conditions may be said to be more prevalent among those whose habits of cleanliness in the past might have been improved—that is, the influence of greater attention to cleanliness has been followed by a lessening of this form of occupational eruption.

Table showing the Results of Five Examinations of Green Shed and Secreting Shed Workmen Combined.

(Workmen in crude paraffin departments and in paraffin refineries.)

Dates of Examinations.	March- April, 1919.	July- August, 1919.	March, 1921.	Sept., 1921.	Feb., 1922.
No. of men ex- amined	188	146	148	113	80
Group 1 ...	79 = 42.0%	65 = 44.5%	73 = 49.3%	60 = 53.1%	31 = 38.7%
Group 2 ...	29 = 15.4%	46 = 31.5%	24 = 16.2%	31 = 27.4%	15 = 18.8%
Group 3 ...	55 = 29.8%	21 = 16.4%	42 = 28.4%	21 = 18.6%	27 = 33.7%
Group 4 ...	21 = 11.2%	11 = 7.6%	9 = 6.1%	1 = 0.9%	7 = 8.5%
Group 5 ...	3 = 1.6%	None	None	None	None

The average frequency of eruption for the five examinations is:

Group 1. Those having no occupational eruption ...	45.5%
Group 2. Those having a mild eruption ...	21.4%
Group 3. Those having a moderate eruption ...	15.1%
Group 4. Those having a severe eruption ...	7.6%
Group 5. Those showing presence of warty growths ...	0.4%

Seasonal Conditions.—As a general rule occupational conditions are worse during winter months. As might be expected, cold, by lowering the vitality of the skin, accentuates old-standing eruptions, especially those of the nature of dermatitis erythematosa and erythema simplex. In the former condition the skin is more roughened and scaly, and the warty excrescences are more numerous during winter and spring than in summer months.

Measures Adopted for the Protection of the Workmen.—During recent years a great deal has been done for the protection of the workmen in the paraffin departments in the various works. These consist of the provision of adequate facilities for ensuring absolute cleanliness of bodies and clothing of the workmen, the use of protective applications for the exposed parts, and regular medical inspection every three months.

Protective Applications.—So far as is at present known, the best protective application is castor oil, especially in its semi-crude thick state. This is insoluble in any of the paraffin series, and so forms an impervious covering for the arms, etc. Before beginning work each workman smears his hands and arms; and

In the last two years Dr. Potter claims to have personally delivered 2,243 cases, and to have performed version on 1,872. In his practice, therefore, almost every condition except those calling for Caesarean section is to be regarded as an indication for version, and this being so it is not surprising to find that the chapter on "Indications" is perhaps the feeblest in the whole book, and displays a lack of judgement. The author states that malpositions of the child were present in more than half his cases. It is of course self-evident from his figures that a very large number of the occipito-posterior positions, at any rate, would have righted themselves if left alone, and probably without undue prolongation of the labour. The author is, therefore, in the main driven back for justification upon his desire to eliminate the second stage of labour to diminish shock and trauma, and to dispel the fear of childbirth from the minds of his patients. We are disposed to think that the dread of childbirth is not so great as Dr. Potter would have us believe. However this may be, the proper administration of morphine and hyoscin does, in British experience, abolish both this fear and all *post-partum* shock.

without risk to either mother or child. The deliberate policy of interference with the natural course of labour in perfectly normal cases is, we hope and feel sure, one which will not commend itself to British medical practitioners. We cannot do other than condemn utterly Dr. Potter's wholesale employment of version, despite the excellent results that the author personally has obtained. At the same time, it seems that Dr. Potter's technique is in some points an advance on the ordinarily accepted method of internal version—in particular, in the avoidance of hurry (and the usual attendant flurry) in delivery of the thorax, arms, and aftercoming head, and in the avoidance of violent methods of resuscitation of a "blue baby." It is well for us to be reminded of the value of version, carefully executed, in many conditions in which at present recourse is had to the forceps operation, almost without thought of any possible alternative. While, therefore, we wholly disapprove of Dr. Potter's thesis, we think that his ardent advocacy of version will have no ill effect upon the teaching of obstetrics—possibly the reverse. Certainly he has produced a book which, however much we may disagree with the teaching, is eminently readable. He is to be congratulated upon the excellence of his illustrations and the charm of his style.

RADIUM THERAPY.

A very comprehensive book entitled *Radium Therapy*,² the work of Dr. FRANK EDWARD SIMPSON, Professor of Dermatology of the Chicago Polyclinic, is intended primarily for those actually engaged in radium therapy, but the author wishes it also to serve as a reflex of the current practice in this branch of medicine. Following upon chapters which touch of radio-active substances and radium itself from the historical point of view, the physics and the properties of the alpha, beta, and gamma rays are described in detail; in chapter vii the author's experimental work on the absorption of gamma rays in water as measured by two types of ionization chambers is set forth, and illustrated by means of diagrams.

There are two chapters on the biologic effect of radium rays which largely consist of a summary of the more important work which has been done by various research workers. References are made to the stimulation of tumour growth by insufficient radiation, but the author's clinical experience has not convinced him that any actual stimulation of tumour growth by radium rays occurs. No doubts, indeed, whether this would be possible under the modern method of large primary dosage. In discussing the problem of immunity to malignant disease it is suggested that it is possible that the different response of similar tumours to radiation depends to some extent upon the systemic defensive powers of the organism, and that the lymphocytic system is of importance in connexion with the disappearance of malignant growths under the influence of radiation. The chapter on dosage is written largely from the mathematical point of view, and the results of many mathematical calculations considered to be of value in estimating the intensity of radiations from different apparatus at different distances are set forth in tabular form.

We come next to the main portion of this book, which deals in separate chapters with radium in general surgery, in gynaecology, in dermatology, in ophthalmology, otology, rhinology, and laryngology; there is also a chapter on the treatment of the ductless glands, and one on radium in internal medicine. Reference is made also to professional injuries due to radium. A bibliography which is comprehensive and takes up nearly sixty pages brings the work to a conclusion. Full-page illustrations of cases before and after treatment afford striking proof of the good results which can sometimes be brought about by radium treatment and serve to emphasize its value as a therapeutic agent. The author shows many examples of naevi and angiomas of the face treated with unusually good cosmetic results.

The book is well printed on excellent paper, and the numerous illustrations are finely reproduced. The general arrangement of its text should make this a valuable book of reference for anyone requiring hints for the treatment of individual cases; and as a whole it is a very complete textbook of the present position of radium therapy.

² *Radium Therapy*. By F. E. Simpson, A.B., M.D. London: Henry Kimpton, 1922. (Roy. 8vo, pp. 391; 166 figures. 35s. net.)

THE CRITICAL AGE.

Dr. ARTHUR LECLERCQ has written an attractive volume³ of the rather depressing subject of the affectional specially prone to appear at the turning point of life when, as he pictures the traveller, having at last reached the summit of the hill, begins to descend, and thereafter does so with increasing rapidity. At this period the organism usually—though there are exceptions, and of course many will consider their case to prove the rule—is beginning to show signs of exhaustion and the functional vigour of the organs is on the decline. The pathology of the critical age is regarded as comprising three main groups of diseases: First, those of endogenous origin, gout and "paragouty" affections, which cover a wide field, and recall Murchison's lithaemia—namely, asthma, bronchitis, and emphysema, eczema, herpes, acne, prurigo, dyspepsia, pharyngitis, tonsillitis, hepatic congestion, mucous colitis, haemorrhoids, renal colic, cystitis, urethritis and calculous pyelocystitis, migraine, facial neuralgia, sciatica, arthralgias, and myalgias. In this first category are also included obesity, diabetes, arterio-sclerosis, and granular kidney. The second group contains the exogenous affections due to infections, such as syphilis, enteric, rheumatic fever, and influenza, fifteen to twenty years previously, the effects of which accumulate and show themselves in cardio-vascular and renal lesions. The third group, the exo-endogenous, due sometimes to an external cause, such as alcohol, lead, or tobacco, or to premature age, does not appear to be a very sharply cut one; it is described as including the manifestations of arterio-sclerosis, such as dyspnoea, angina pectoris, cerebral attacks, and uraemia. The lesion is referred to as the result of the rust of life and as attacking the internal coat alone of the vascular system. Descriptions are given of gout, "paragouty" affections, and obesity; on the first page of the section on the pathology of gout there is a well-merited tribute to the labours of British physicians, among whom Murchison, Liff, Dyce-Duckworth, and Latham have suffered from the printer's unfamiliarity with our spelling.

An interesting, if not entirely convincing, distinction is drawn between obesity in males which is regarded as alimentary, and that in women which is in the main referred to toxæmia caused by ovarian or polyglandular defect and by failure to eliminate the poisons in the menstrual flow.

It should be explained that this is a first volume of a new edition of a work on the diseases of the fifties published by the same author eleven years ago and reviewed in the second volume of this JOURNAL for 1911, p. 74.

AN INDEX OF THERAPEUTICS.

It was a happy idea to include in the series of Oxford Medical Publications a volume such as the *Oxford Index of Therapeutics*,⁴ edited by Dr. VICTOR E. SORAPURE. The purpose of the book is, in the editor's words, "to extend the interchange of ideas and of the methods of practice of each of the great branches of the English-speaking practitioners of medicine." Dr. Sorapure claims to have had exceptional opportunities of judging the needs and interests of both British and American doctors, and no one will deny the justice of his claims. The book is designed first, foremost, and all the time as an up-to-date book of reference for the general practitioner, embodying the best teaching of England and America. With this object the editor has secured the services of a number of distinguished contributors from Great Britain and the United States, all of them recognized as authorities on the subjects with which they treat. The aim of each of them is to give simply and briefly what he considers to be the best method of dealing with the particular condition he may have under review.

The work is arranged in four sections. Part I, on methods, occupies by far the largest portion of the volume. It consists of a series of monographs arranged in broad groups wherever the clinical relation is such as to justify it. Thus, under "Obstetrics" we find discussed the treatment of all the normal and abnormal conditions pertaining to pregnancy and parturition; similarly with genito-urinary conditions, diseases of children, heart conditions, and so forth. Such subjects as do not fall conveniently into those groups are arranged in alphabetical order. The editor insists that "the alphabetical

Demy 8vo, pp. xvi+

1126; 109 figures. £2 2s. net.)

order . . . is not intended to serve mainly for purposes of reference. This is the function of the index." It must be conceded that there are certain advantages in arranging the subject-matter in this way. For instance, it admits of a subject like radio-therapeutics being dealt with in a thoroughly comprehensive manner under a single heading. But on the other hand, a book of this kind is more often used for making a reference to some particular subject, possibly in the course of a round of professional visits, rather than for continuous reading. A strict alphabetical arrangement such as is generally adopted in works of this character will generally be found more simple and expeditious by the reader and will frequently save him any necessity to refer to the index. This is only a minor criticism of the manner in which the matter is presented.

As regards the subject-matter itself nothing but praise can be accorded. The names of the authors are sufficient guarantee for the soundness of the advice given, and it is amazing how much valuable and practical information has been crammed into the space available. Only those methods of treatment which are by common assent agreed to fall within the province of the general practitioner are recommended. The teaching throughout is based on accepted principles and well-tried methods, and therapeutic stunts find no place in these pages. Where need arises, useful illustrations, generally in diagrammatic form, have been inserted in the text. Part II is a pharmacopoeia of those drugs only which have been mentioned in Part I, while in Part III these drugs and preparations are classified under their pharmacological properties. The practitioner should find Parts II and III most useful as adjuncts to Part I. Part IV consists of an excellent index which permits at once easy and rapid reference being made to any subject in the text. It can truthfully be said that the editor and his collaborators have worthily achieved their object in providing English-speaking practitioners with a handy and reliable book of reference. They are heartily to be congratulated on the successful result of their labours.

NOTES ON BOOKS.

MESSRS. OLIVER AND BOYD have issued a fifth edition of a folder entitled *Income Tax—Tabular View*.⁵ It is a concise statement, has evidently been carefully prepared, and supplies a mass of useful information in a most accessible form. The tables include the past and present rates of income tax and super-tax, the money value of various totals of allowances, and the tax borne on and the gross equivalents of various net (that is, tax-free) dividends; but most taxpayers will find even more useful those sections which are designed to set out as briefly as possible the various claims which can be made, or the thirteen succinct paragraphs of reminder and advice. It should be said that in the main the information given is directed to enabling the reader to ascertain the proper amount of tax payable in various circumstances on a known amount of income; even the ingenuity of the authors could hardly provide, within the limits necessarily set by conditions of production, much information on points arising on the ascertainment of the amount of the income to be assessed, though it is in that connexion that the need for a concise means of reference is sometimes most keenly felt.

In *Paris à la Carte: Where the Frenchman Dines and How* Mr. SOMMERVILLE STORY⁶ supplies a real want by conveying the information so essential to visitors to the capital which he designates as the city *par excellence* of restaurants. He writes in a pleasant, gossipy strain, with anecdotes about the history of the famous restaurants, cafés, and houses, their proprietors, habitués, and special plats. The atmosphere of Paris is so successfully created in the first chapter on "the apéritif hour" that many readers will mentally eat their dinners over again with a pleasant sense of reminiscence. The ground is fully covered without tiresome detail, and all tastes are catered for. *La Tour d'Argent*, whither only true gourmets go, and which, as it never advertises, is little known to the ordinary tourist, and Duval's numerous establishments, where it is still possible to get a modest meal, with half a bottle of wine or mineral water, at a reasonable price, receive equal attention. There are attractive chapters on "The traditions of *la haute cuisine*," and on "The romance of some famous dishes." When a second edition appears—and it cannot be long before it is called for—an index would add to its utility, though it would be difficult to increase its charm.

THE HEALTH AND HEALTH ADMINISTRATION OF ENGLAND.

(Continued from page 384.)

In continuing our notice of Sir George Nowman's report on the State of the Public Health in 1921 we may take next the section dealing with tuberculosis.

TUBERCULOSIS.

The basis of preventive action is laid down as twofold—first, to fortify the powers of resistance by nutrition, hygiene, and immunization, and secondly, to prevent spread of infection by persons or materials, including meat and milk. Steady progress is claimed for this policy in 1921, especially as to (a) earlier notification, (b) selection of patients for institutional treatment and in its duration, and (c) economical utilization of the various parts of the national system. A substantial reduction of expenditure is hoped for, with reduction of the disease.

Following the war increase in the mortality there was a rapid drop in 1919 to the lowest rate on record, and a further considerable fall in 1920. In 1921, however, there was a small rise in deaths from phthisis, though in those due to other forms there was a small decrease. Sir George Nowman suggests that the increase may have been associated with unemployment and inadequate nutrition, as illustrated in Germany and Poland.

Notifications of new cases, both pulmonary and non-pulmonary, were in 1921 the lowest on record, though the rate of diminution was not so rapid as in the two previous years. Notification is still incomplete and delayed. At Barnsley 87 per cent. of the fatal cases were either unnotified or notified only within six months of death. At Bath, of 54 fatal cases only 35 had been notified, 9 of them within three months of death. In one district 208 of 350 notifications were not received until after the stage when a cure could be expected, owing to delay either in getting a medical opinion or in recommendation for treatment. In Lancashire, however, 70 per cent. of new cases were intimated for the opinion of the tuberculosis officer before notification. Examination of contacts is still insufficiently carried out, sometimes owing to want of staff, but often because cases are retained too long at dispensaries instead of being handed over for domiciliary treatment subject to occasional consultation with the tuberculosis officer.

Tuberculosis Schemes.

Dispensaries number 421. Residential institutions are 443, of which 210 are provided by the local authorities, and the rest are voluntary. The beds in the former are 11,262 and in the latter 7,681, a total of 18,943. Owing to local circumstances a considerable margin are at any given date unoccupied.

Administration often lacks co-ordination; "there is still in many areas too much of the out-patient room atmosphere in the dispensary, too little examination of contacts, and insufficient preventive work." The tuberculosis officer should be in close touch with the general practitioner, who should treat as many cases as possible at home. The officer, it is pointed out, should consult with the practitioner and use the reports under the Medical Benefit Regulations; he should also report his periodical examinations to the practitioner. Valuable as are the reports of health visitors, the tuberculosis officer should occasionally visit himself, but this is not done everywhere. Supervision of patients using shelters should be effectively carried out.

Sanatorium benefit was transferred on May 1st, 1921, from the insurance administration to the county or county borough councils; and the Public Health (Tuberculosis) Act of 1921 imposed on councils the duty of providing treatment schemes, and circulars and regulations were issued for the new arrangements. Preferential treatment of ex-service men has been continued.

The reports of a number of medical officers of health lead to the opinion that the proportion of persons alive and employed five or more years after residential treatment is relatively large, looking to the late stage at which the majority came under treatment, and "residential treatment should not be lightly condemned as a failure—rather we should be encouraged that the results have been so good." It may prolong life and working capacity, even where admission is at too late a stage for arrest.

Care and After-care.

Investigation by the Ministry shows that excellent work is being done. The sociological problems require early treatment as well as the patient. Various pertinent hints are given as to training sections for ex-servicemen; 410 places have now been provided, and will shortly be occupied. They are intended to teach men to work on their own account in suburbs, country towns, or villages, at market gardening, rural carpentry, furniture repairing, house repairing, tin-smithing, rush and basket making, jewellery, and watch and china repairing. It is not expected that the work will be commercially successful at once; the men are mostly damaged veterans. The new plans differ from industrial colonies in that the men will have to return to normal competitive life.

In his conclusion as to tuberculosis Sir George Newman says: "The solution of the problem will be found in a social revolution, in the broad acceptance of the way of health, omiciliary and industrial. Tuberculosis is a harvest, the effect of a cause, a seed sown in a favourable soil. We must restrict the seed sowing, and we must make the soil unfavourable and resistant."

GENERAL EPIDEMIOLOGY.

In classifying preventive measures Sir George Newman places sanitary environment first, individual resistance second, and avoidance of infection third.

Small-pox.—The number of cases of small-pox notified was 343. Of these 7 were notified at ports; 23 more were discovered, 3 of them at ports; 39 notifications were withdrawn on revision of diagnosis, so that the net total was 3.6. The centres were Nottingham, Middlesbrough, and the Colne Valley. The Nottingham area had 142 cases with no deaths. School children to the extent of 42 per cent. were unvaccinated, but 10,000 persons were successfully vaccinated or revaccinated at the public expense. In the Colne Valley there were 94 cases of a mild type, but a group in the New Forest was of virulent type, and vaccinal condition made the usual distinction. The same remark applies to a statistical table relating to the cases throughout the year. The term "alastrim" was used in reporting three of the cases.

Enteric Fever.—Details of a serious outbreak of enteric fever at Bolton-upon-Dearne and contiguous districts in the West Riding are published in our note on Dr. W. Vernon Shaw's special report to the Ministry (BRITISH MEDICAL JOURNAL, July 8th, 1922, p. 56). *Salmonella* caused various small outbreaks in the course of the year.

Scarlet Fever.—The number of notifications of scarlet fever was 7,073, an increase over 1920. The disease was mild and the mortality low. Administrative measures in scarlet fever are being considered by the Ministry in view of the heavy call the disease makes on institutional accommodation.

Diphtheria.—Stress is laid on the Schick test. The classification of carriers in accordance with their infective ability is receiving attention. Emphasis is laid on the advisability of giving antitoxin as soon as a diagnosis is reached on clinical grounds, without waiting for the laboratory report; the minimum initial dose, it is thought, should be 8,000 units, followed by another administration twelve hours if notable improvement has not occurred.

Influenza.—The report on this disease covers, in addition to 1921, the first quarter of 1922, as the epidemic which began in October, 1921, only then attained its climax. In the early part of 1922 the season was very little prevalent. The last outbreak, it is said, bore the same relation to the pandemic of 1918 as did the epidemic of 1919 to the pandemic of 1922. In the recent epidemic few visitors to the country remained ultimately unaffected. The rain was less severe than in 1918-19; lung involvement was comparatively infrequent; fatality was most marked at the two extremes of life, and generally the type was inor pandemic, though gastro-intestinal disturbances were rather frequent, especially in the northern and midland areas. Rashes also occurred, and there are instances in which jaundice in children preceded the epidemic by four or six weeks. But the main stress was on the respiratory system, though pneumonia was not specially eminent.

Encephalitis lethargica, poliomyelitis, poliomyelitis, and cerebro-spinal fever are briefly reported. The number of cases diagnosed as poliomyelitis during the last three years; also occurred. Poliomyelitis is also more frequent than in the previous year, but cerebro-spinal fever showed a steady diminution from 1915, when the number was 2,566, to 1921, when it was only 411. The Ministry has been co-operating with the Medical Research Council in trying to get an effective curative serum against Type II meningococcus.

RELATION OF FOOD TO HEALTH AND DISEASE.

Milk.—The conditions of milk production in seventeen districts were examined. Producers of "certified" milk (the highest standard) increased from 9 in 1920 to 23 in 1921, and of Grade A milk from 11 to 15. Retailers of the former increased from 7 to 44, of the latter from 5 to 6, and of both from 3 to 5. One producer's licence was revoked. Bacteriological standards, as for "certified" milk, are found very cautious, and less troublesome to supervise than the detailed

requirements for Grade A, which ought also to have bacteriological standard. The National Institute for Diet Research at Reading is doing good work.

Meat Inspection.—The report of the Departmental Committee, published in July, showed that there is no conflict between public and legitimate trade interests. The Committee agreed that better and more uniform inspection at slaughtering is needed, and can be carried out economically. Sanitary inspectors should be specially educated in such work. Facilities for practical study are being extended by larger authorities.

Food-poisoning inquiries have been the subject of arrangement with the Medical Research Council, and medical officers of health have been circularized. Various outbreaks were reported, and some were investigated under the arrangements made. Two instances of belladonna poisoning were met with, one of them due to eating rabbit snared where belladonna grew; in this case atropine was found in the liver.

Sale of Food and Drugs Act.—Over 113,000 samples were reported on by public analysts; 6.7 per cent. were found to be adulterated, as against 7.1 in 1920. The percentage of milk adulteration found was highest in Sheffield, Birmingham, Salford, and Derbyshire, and lowest in Derby, the extremes being 10.97 and 1.85. The difference between the average composition of milk and the standards under the Sale of Milk Regulations gives the adulterator a margin to work on.

(To be continued.)

BACTERIOLOGY OF PNEUMONIA AND INFLUENZA.

THE Ministry of Health has issued a report* containing the contributions to the study of pneumonia and the pneumococcus and one on the serological characters of influenza bacilli.

Pneumonia.

Pneumonia is a disease which calls urgently for further bacteriological study because it is a substantial cause of national mortality. In 1921 it was primarily responsible for 34,708 deaths in England and Wales, apart from those due to diseases in which it is the chief secondary complication, such as measles, whooping-cough, and influenza. Moreover, the important advances achieved by the grouping of pneumococcus types and the preparation of antisera against each group have already resulted in modifications in the treatment of this disease and a considerable reduction in the mortality of those cases in which it was possible to administer an appropriate serum. Attention has been frequently directed in the pages of this JOURNAL to these researches as they have been published. The report before us contains a concise historical account of what has so far been achieved, together with an account of further contributions to the laboratory study of allied problems. When the international conference on the standardization of serums and serological tests was held in London in December, 1921, it was agreed that international co-operation was needed to ascertain the distribution of different types of the pneumococcus and to determine the best criteria for the production of effective therapeutic serums. The report answers some of the questions raised at that conference and indicates lines for further investigation.

The first report by Dr. Arthur Eastwood, entitled "A brief review of recent bacteriological work on pneumococci," points out that in the earlier work, to which Washburn and Eyre made important contributions many years ago, attempts were made to produce antipneumococcus serum of therapeutic value, but it was not until Neufeld and Handel in 1912 demonstrated that pneumococci could be divided into groups that much progress was made; they showed that an immune serum was not possessed of any protective qualities except towards the same group against which it had been prepared. Investigations at the Rockefeller Institute subsequently showed that pneumococci could be divided into four groups, of which Types I and II possessed sharply defined serological characters and were rarely encountered apart from disease. The American Type III, or *Pneumococcus mucosus*, had distinctive morphological and cultural characteristics and was found to occur commonly in normal mouths. A large number of other strains were found which exhibited a great diversity of serological reactions, and did not belong to any of the above groups; this heterogeneous collection was termed

* See BRITISH MEDICAL JOURNAL, 1921, vol. ii, p. 341.

* Reports on Public Health and Medical Subjects, No. 13. Bacteriological Studies on Pneumococci and Influenza. London: H.M. Stationery Office. To be obtained through any bookseller. Price 2s. 6d.

Type IV. The following table shows the frequency with which these types were encountered and their virulence:

		Incidence per cent.	Mortality per cent.
Type I	...	33	25
Type II	...	31	32
Type III	...	12	45
Type IV	...	24	16

The Rockefeller workers were able to produce a serum efficacious only for Type I infections, and in these infections the mortality has been reduced to 10 per cent. The serum must be given intravenously in doses of 90 to 100 c.cm., repeated every eight hours until there is a satisfactory fall of temperature and improvement in the symptoms. In infections due to Types II, III, and IV no benefit followed administration of serum prepared against these strains.

Dr. Eastwood's review of the researches of other workers brings out certain facts of considerable importance. Thus it has been found by employing the absorption tests that serological relationship exists amongst strains which are usually regarded as antigenically distinct, and that prolonged culture in homologous serum may modify profoundly the agglutinability of different strains; these changes in the serological reactions are accompanied by loss of virulence and reduction of antigenic capacity. That there may be little relationship between agglutination titre and protective power in a serum is another fact emphasized by many workers.

Although the Rockefeller investigators were only able to produce a protracted serum against Type I infections, other workers employing different methods claim to have produced antipneumococcus serum protective against all strains. An entirely new departure in serum therapy has been made by Preston Kyes, who appears to have cured human pneumonia by the injection of serum from fowls immunized with massive doses of pneumococci. Truche has described a method for preparing a polyvalent antipneumococcal serum by inoculating horses with an antigen treated with alcohol and ether. The apparent diversity of antigenic structure amongst strains of pneumococci presents difficulties which have not yet completely been overcome, but there is an indication that ways out of these difficulties may be found, and the benefits of serum treatment secured for all forms of pneumococcus infection.

The second paper is by Dr. Frederick Griffith on "Types of pneumococci obtained from cases of lobar pneumonia." In order that workers in different parts of the world may be able to compare the results of their investigations into the prevalence of types of pneumococci in different countries and at different seasons it is necessary that some uniform method be adopted for the isolation of the organism, the preparation of the agglutinating serum, and the carrying out of the test. Dr. Griffith makes the following suggestions towards the formulation of a uniform diagnostic test. Since much confusion has already arisen from the comparison of results obtained by fundamentally different methods, he recommends that a standard method should be based on that of the Rockefeller Institute, the results of which have been confirmed in many countries. He considers it preferable that the pneumococcus should be isolated by the intraperitoneal injection of a mouse and the recovery of the organism from the heart's blood rather than by direct plating on laboratory media, one reason being that more than one type of pneumococcus may occur at the same time in the sputum, and the predominant virulent type, which will multiply in the mouse, is most likely to be the cause of disease in the human being. His experience indicates the value of the following technical details:

1. The suspensions used for agglutination should be whole broth cultures, since they give the sharpest results.
2. Agglutinating serums should be prepared in the rabbit, since this animal yields the most specific serums.
3. Strains used for immunization should be maintained in virulence and should therefore not be subcultured for long periods on solid media.

In a series of 150 cases of lobar pneumonia, taken mainly from the London area, Dr. Griffith finds that the American Types I, II, and III occur in about the same proportion as in the United States, and he agrees that these types are serologically distinct. There remain, however, a large number of strains which differ from these three types and present many varieties amongst themselves. These unclassified strains are placed in Type IV, and it is interesting to note that these organisms are responsible for cases of pneumonia somewhat more frequently in this country than in America. In carrying

out protection tests in mice the test culture should be administered intraperitoneally to ensure accuracy of dosage; such protection tests confirm the serological independence of the types of pneumococci. Protective serums act equally well, whether inoculated subcutaneously or intraperitoneally, and whether the test culture is injected immediately after the serum or after an interval of eighteen hours. The mode of action of antipneumococcal serum is still unknown, since it has been shown by absorption tests that there is no firm union between antigen and antibody and no apparent neutralization of the protective properties.

The third report is by Dr. Eastwood on "The significance of serological differences amongst pneumococci." Here are passed in review all the current general ideas about antigens and antibodies, these being considered from both the chemical and physical points of view. In Dr. Eastwood's opinion the "mosaic pattern" theory, or theory of multiple antigenic components, as an explanation of the nature of antibodies and their relation to antigens, has been pushed a great deal too far. Though of value in explaining the behaviour of other groups of bacteria showing some serological relationship, it is definitely an encumbrance when applied to the four groups of pneumococci which in their serological reactions appear to be so independent. It may be that the common antigenic element probably present in all strains of pneumococci is masked in each group by the acquirement of some secondary factor which prevents the characteristic response to the common antigenic element. There is always the possibility, also, that the pneumococcus may be changed in the living body from one type to another, for the persistence of type in prolonged subculture does not show that mutation cannot occur in the living body. The practical question involved is whether or not it will be possible to produce antipneumococcal serum for strains other than those belonging to Group I, and on this subject Dr. Eastwood expresses himself as follows:

"I think the study of serological differences amongst pneumococci has not led to any final conclusions such as would justify the opinion that no serum will be therapeutically efficacious unless it contains an antibody corresponding to the antigen which is peculiar to the infecting strain."

Influenza.

The fourth report, by Dr. W. M. Scott, deals with the distribution and serological characters of influenza bacilli and embodies the results of a study which has extended over the four years 1918-21, of which the main conclusions are:

1. Influenza bacilli have been recovered from the normal nasopharynx in over 30 per cent. of persons examined.
2. Influenza bacilli have been found in the sputum or lung in about 60 per cent. of cases of lobar pneumonia, in 88 per cent. of cases of simple bronchopneumonia and bronchitis, and, during the epidemic of January, 1922, in 65 per cent. of cases of influenza and influenzal pneumonia.
3. Agglutination tests have revealed great diversity in serological types, but certain common antigenic characters occur in a proportion of the different strains.
4. There is no satisfactory evidence of special serological types being associated with disease nor with epidemic prevalence of influenza.
5. The serological diversity of influenza bacilli cannot be used as an argument either in favour of or against their etiological relationship to influenza.

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on Tuesday, July 11th, 1922, 23 cases were considered and £273 voted to 20 applicants. The following are a few of the cases relieved:

Widow, aged 40, of L.R.C.P. and S.Edin. who died from pneumonia in February last. She is left with two boys, aged 9 and 6 years. From February she has earned £9s. from fees for teaching piano and singing, and has received £25 10s. from investments. When the estate is realized applicant expects an income of £150 to £200 a year. She asks for assistance towards the education and keep of the two boys. Voted £2, and the case referred to the Royal Medical Benevolent Fund Guild.

Widow, aged 68, of L.R.C.P. and S.Edin. who died in 1933. She suffers from ill health and failing eyesight. She has no income now, and is living with a widowed daughter who has to maintain herself and her two children. Voted £18 in twelve instalments.

Daughter, aged 61, of M.D. Edin. Had to give up dressmaking business owing to ill health and want of money. Applicant's eyesight is bad and she can only work two or three hours at a time. Voted £18 in twelve instalments.

Daughter, aged 42, of L.R.C.P. Lond. who died in 1901. She has phthisis. At present she is a lady help at a small salary as she is not strong enough to do much work. Voted £18 in three instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1.

British Medical Journal.

SATURDAY, AUGUST 26TH, 1922.

"THE WRONG TURNING IN PUBLIC HEALTH."

It is curious to note how the present financial stringency is influencing current literature on public health. Without doubt it was constantly present to Sir George Newman when he was writing his report on the state of the public health in 1921, and not less to Professor Wynne and Dr. Fremantle, M.P., when they were composing the papers they read before the Section of Public Health at the Annual Meeting at Glasgow. These papers are printed in full in this issue, and, together with Sir George Newman's report,¹ form a symposium which cannot but stimulate, though perhaps also a little bewilder, the reader anxious to clear his conception of the profit and loss account presented by sanitation and preventive medicine. Sir George Newman writes under a sense of official responsibility; Dr. Fremantle is not only a member of Parliament, but a consulting medical officer of health, and Dr. Wynne is both medical officer of health for Sheffield and Professor of Public Health in the University of that city. Each in his own way has the same purpose at heart—that while the country shall get the best possible return for its expenditure, and unprofitable outlays shall cease, there shall be no paucity of work making for communal welfare.

It is the last-named object that Dr. Fremantle has especially at heart. He demonstrates by a series of propositions and calculations that sickness and disablement are immensely costly to the nation. Under the Insurance Act in England and Wales the time lost by the employed male population in the year 1921 was equivalent to a year's work of 178,000 men. He accepts Farr's conclusion that the total number of sick throughout any year is about double the deaths occurring in the year, and this figure applied to 1920 would give a total of over 900,000 sick and disabled. Under this heading he calculates the loss at £50,000,000 per annum. Care and treatment in institutions must cost, roughly, another £50,000,000, while treatment and maintenance of home cases would add a further heavy burden. After allowing for various deductions, he estimates the total direct material loss to England and Wales from sickness and disability at £150,000,000 a year. Taking note of the reduction of death rates in sixty years, he calculates, roughly, that the money saved thereby is over £62,000,000 a year. But the life-table expectation of the working period beginning at 20 years—the age of productive labour—has increased by 10 per cent. in the seventy years ending 1912, and as the national income from personal services is reckoned at two thousand million pounds, the 10 per cent. increase means two hundred millions a year. The elimination of tuberculosis, if it were possible, would, on a conservative calculation, add over ninety millions a year from personal services to the national income. In the United States the estimated loss of wealth from tuberculosis is £100,000,000 a year; the total cost of sickness and deaths is about six times as much, and one-third of it is regarded as preventable.

Dr. Fremantle wisely concludes his paper on a note of warning. "Many measures," he says, "put forward in perfect good faith by experts and by the public are not yet sufficiently substantiated to merit their adoption as 'effective.' Many are advocated too much from the

standpoint of those who seek to raise the material comfort of the workers out of the Exchequer. While improvement of feeding and of other social conditions may be expected to diminish tuberculosis and improve health, it might have a precisely contrary effect if the method adopted were to undermine initiative, moral, and personal care of the individual."

Professor Wynne, in his paper with the striking title, "The wrong turning in public health," has been thinking on different but parallel lines. For him the wrong turning was taken when ideals of prevention were allowed to be obscured by solicitude for the treatment of individuals already diseased. His argument may, we think, be briefly stated to be that the chief cause of communal disease is poverty, that poverty is increased by waste and excessive taxation, and that, therefore, every penny spent on public health, on education, or any other object admirable in itself, is waste if not justified by results. Waste, he contends, is enormously multiplied when individuals are dealt with instead of their periphery. Endless committees and national councils are created and much energy expended, but Dr. Wynne finds a rather cynical consolation in the thought that the money they waste would otherwise be wasted on something else. He is on sure ground when he maintains that popular clamour for eleemosynary schemes should be resisted, and enthusiasm guided by expert criticism. Public opinion would not tolerate refusal to finance any proposal certainly useful, but at present money is lavished on schemes of which it cannot be said that this is true.

Professor Wynne demurs to Sir George Newman's dictum that "the centre of gravity of public work must swing more and more from the environment to the individual," though he is ready to admit that national health insurance, maternity and child welfare, school medical work, free treatment of venereal disease, are all laudable in intention, but directed to the individual, whilst the whole of our housing schemes broke down for want of money, and slum conditions are engendering diseases in quantities "which our breathless efforts at dealing with end results are powerless to overtake." The old ways—improvements of environment—were better. But when unduly depressed by such thoughts Dr. Wynne finds consolation in reports showing that conditions in Sheffield were much worse in 1846. He describes them vividly, and, coming to recent times, he admits that in the decline of infant mortality since 1870 "the individualistic school of public health has its greatest triumph." Ingeniously, however, he claims that as the child's environment is its mother, infant welfare is after all environmental, whilst formerly the management of infants was a "tradition expounded by the handy woman and her colleague the lady next door," and after the child was weaned (here we are again driven to quotation) "the only available food was the emulsion of cowdung and house-flies known as fresh milk." Of tuberculosis he says that the whole administration is "a classic example of the ill effects of neglecting environment in favour of dealing with the individual," and he declares his disbelief in the assertion that training inculcated during three months in a hospital or sanatorium would neutralize the increased opportunity of subsequently disseminating the disease during the slight prolongation of life when the patient returns to his home. When open-air treatment and sanatoriums were boomed there was "an outbreak of 'national societies,'" which demanded immediate provision of sanatoriums for all, "and this to a great extent was done" at a time when there was money to burn. But now we are, Dr. Wynne avers, spending some ten millions a year "when there is no money available for the elimination of the insanitary areas, where we cultivate more tuberculosis in a week than all the sanatoriums could house in a year."

¹ See page 323 of our issue of last week, and page 387 of this week.

Next, as to the school medical service, he urges that "the number of cases of disease treated in one generation will not lessen the number of defects in the next," whilst the admitted improvement in personal cleanliness (which is much less in districts known to Dr. Wynne than Sir George Newman claimed in 1917 for London, Torquay, and Carlisle) "is something imposed upon the parents by the authority, not emanating from themselves, and therefore not indicating an advance in civilization." He regrets that the Ministry's chief medical officer, who was deeply impressed with the importance of environment in 1917, wrote in 1920 that "the school medical service finds its fulfilment only in the service it can render to the individual child." But his own early experience of publishing an accurate survey of the sanitary conditions of the schools in his area taught him how painful this subject would be to "educationists."

His general conclusion is that "we have turned away from the ideals of the Public Health Act" long before environmental work was completed, and "that we are bleeding the taxpayer and the ratepayer by expenditure that does not give an adequate return in improved health and prolonged life; that we are undermining responsibility by providing services at the public expense which should be paid for by the individual, and incidentally depriving the private practitioner of a large part of his legitimate opportunity of exercising his calling." Professor Wynne has, in fact, delivered in terse and vigorous terms a bold attack on many aspects of latter-day policy in health administration. No one can refrain from sympathizing with some of his regrets and aspirations. He longs for a strong housing policy, and so do we all. It is not necessary to contest his view that the money spent on the treatment of cases of tuberculosis would have yielded a richer harvest if it had been devoted to the clearing away of slums and their substitution by good healthy dwellings. Neither, for the present purpose, need it be denied that disappointment has damped the hopes and the enthusiasm of any who made the largely erroneous assumption that because tuberculosis is an infectious disease it could be successfully controlled by the isolation and institutional measures which have, on the whole, been so valuable in the case of the acute zymotics. Whether Professor Wynne is right in holding that even three months' sanatorium treatment does not accomplish Sir Arthur Newsholme's purpose of educating the tuberculous patient against spreading infection when he returns home we do not pause to discuss. But, be the school of infectionists right or wrong, we do not think any of them would admit that the demand for "sanatoriums for all" has even yet been met, nor is there any probability, under existing conditions, that it ever will be met. Is it not far more probable that the money, had it been devoted with business economy to housing schemes, would have given better results?

This brings us to the consideration of a very essential political question. Supposing not a penny had been spent on tuberculosis dispensaries or sanatoriums, farm colonies, domiciliary treatment, or after-care, would the money so saved have been devoted to housing? Would the price of the box of spikenard ointment have been given to the poor? Was the country alive to the need for housing reform? Professor Wynne writes graphically of the despair and indignation which seize the health officer to-day when he visits insanitary property and realizes the acquiescence in squalor and filth displayed by the present generation. It is all too true; but has it not been at least equally true at any time since the present public health service began? Neither house owners, nor rent payers, nor local health authorities realized in the past the importance of thorough housing reform. When the country was

wealthy it would not open its eyes; now they are open it is poverty-stricken. When, two or three years ago, the politicians and the press and the public outvied each other in their shoutings for houses, what was the result? The Government took up the matter, and with the enthusiastic support of builders and brickmakers and bricklayers entered on a course of reckless extravagance, which was brought to a stop when the nation came to realize that this was a post-war method of fleecing it, such as had hardly been surpassed by the great army of profiteers during the war itself. Straightway prices began to fall, and now houses can be built for half, a third, or even a fourth of what the country had to pay for grandiose schemes which played into the hands of extortionists. Dr. Wynne's own well-recounted experience with regard to schools illustrates another phase of the same question. The "educationists" were not ready for new school buildings, so he desisted, and has advised others similarly, but surely it was right to institute school medical inspection even in defective buildings. The fact is that a public official cannot usefully go too far in front of his controlling authority, local or central; if he does he runs the risk of acquiring the reputation of an amiable visionary, and will accomplish nothing. Dr. Wynne says that increased personal cleanliness of children "imposed upon the parents" does not indicate an advance in their civilization, but what would he have? Should the children of uncivilized parents be allowed to remain verminous (and so infect the offspring of the civilized) until the fathers and mothers learn—if ever they do—to appreciate cleanliness for its own sake? Will not the children by the very imposition on them of cleanliness be civilized in that respect and be the means of civilizing the next generation?

But let us not be misunderstood. We rejoice in Professor Wynne's brilliant attack, and enjoy his hyperbole, as in that entertaining description of fresh milk already quoted. In particular he is right—and here he is in entire agreement with Dr. Fremantle, and has also the sympathy of Sir George Newman—in insisting that there should be the most strenuous avoidance of the sapping of personal and parental responsibility by the bestowal of gifts of food and milk and medicines, unless in cases of the most absolute necessity. Here, indeed, is a real danger, and the Americans are becoming alive to it as well as ourselves. Education of mothers in the nursing of their babies and the rearing of their children is excellent, but when it is avoidably supplemented by doles in money or in kind it is to be condemned. Government grants in aid of local authorities have two sides—an evil and a good. The evil side is that they foster the vicarious benevolence of sloppy sentimentalists everywhere, who argue that as only a half or a quarter of the cost falls on the local rates, and the rest is obtained from the national purse, there need be no hesitation in a free distribution to all concerned of everything they can be plausibly alleged to need. That, however, opens up a wide question which cannot be entered on here.

SHELL SHOCK.

In our last issue (p. 322) we published a summary of the Report of the War Office Committee of Inquiry into Shell Shock. As we then said, it is a document which will appeal to a wider circle of readers than those comprised within the medical and military professions. The report is unanimous, and this somewhat unusual result of an inquiry on a subject which has aroused a great deal of public attention ought to enhance the value of the conclusions reached. Whatever may have been the immediate motives that led the Government to institute the inquiry, there can be no doubt that one of the most

influential was the fact that a feeling of dissatisfaction had been expressed in certain quarters with regard to the treatment of mental disorders amongst ex-service men where the disorder was supposed to have been produced by shell shock. We seem to remember that when the Committee was appointed certain newspaper criticisms were levelled at its constitution, one being that regimental and other combatant officers were not sufficiently represented, and that there was an undue preponderance of medical members. Whatever weight there may have been in this criticism—and we are not to be understood as admitting that it had any—was compensated by the fact that among the witnesses examined by the Committee were many combatant officers, as well as some actual sufferers from the condition under consideration. The nature of the conclusions reached by the Committee, and the fact that its members were unanimous, will, we venture to hope, dissipate any feeling of the kind we have indicated.

The conclusions reached by the Committee are, indeed, identical with those generally reached alike by medical observers and combatant officers who have had any extensive experience of shell shock, whether in patients under their care or in soldiers under their command. The very fact that the conclusions stated by the Committee are similar to those reached by those best qualified to judge may, however, possibly diminish the effect of the report on those members of the general public whose indiscriminate sympathy with the victims of so-called shell shock has done much to perpetuate their condition. When we come to examine carefully the Committee's recommendations and conclusion, it is significant to find that the very term "shell shock" is whole-heartedly and unanimously condemned. The number of cases which could be held to be due to actual concussion from the results of shell explosions were found to form a very small proportion of the total; the proportion is variously stated by different witnesses, but no witness puts it higher than 10 per cent. of the total number of cases from all causes. From the facts and evidence before it the Committee concluded that by far the greatest number of cases are produced by emotional disturbances, to which the effects of fatigue and the general nervous and mental exhaustion induced by strains and hardships of every kind are rightly held to have contributed. The particular kind of emotional disturbance principally to blame is naturally that of fear. The evidence of all observers, especially of those whose duty kept them in or near the front line, is unanimous on this point. To the emotion of fear is added the mental conflict naturally engendered between that emotion and the rival forces of discipline and moral. A third group of cases consists of men suffering from definite mental disorder. The attempt of some members of Parliament, backed up by certain newspapers, to make capital out of the fact that ex-service men have been and are being treated in asylums, received no support from the evidence of witnesses, military or medical, who were closely examined on the point; nor is it countenanced by the Committee, whose conclusions it may fairly be hoped will do something to alleviate any public anxiety on this score. One very eminent authority, indeed, went so far as to say that "the war created nothing in the way of psychoses," and another stated that those service patients who were still in asylums and whose histories he had been able to follow, were nearly all suffering from dementia præcox.

The immense importance of the condition loosely termed "moral" in the prevention of shell shock was emphasized again and again in the evidence given by combatant and medical officers alike, and the Committee wisely points out how moral can be fostered by careful training and discipline. The very great practical diffi-

culty in distinguishing between shell shock and actual cowardice was discussed by several witnesses, who showed themselves fully alive to its importance. In civil life it is often far from easy to decide in certain cases between hysteria and malingering; in the field similar difficulties are encountered when men are charged with cowardice. Unfortunately the Committee has done little to enlighten or guide us on this matter, and we gather that in actual practice it often became impossible to rebut a defence of shell shock.

As was to be expected, some divergence of opinion emerged with regard to the merits of the various methods of treatment, but one of the main conclusions reached is that it is better to keep such cases as far as possible in the divisional areas; men invalided away from a war area and retained for long in hospitals at home rarely recovered sufficiently to return to the line. Much harm was done also by the frequent transfer of men from hospital to hospital, a policy which made continuity of treatment impossible. While the great value of psychological treatment is recognized the weight of opinion is not in favour of the Freudian method of psycho-analysis; emphasis is laid rather on the therapeutic advantages of occupation and re-education.

Methods of recruiting and the deficiencies of the British system, both in peace and war, receive full consideration in the report, and the Committee has provided some valuable suggestions in regard to the principles of training. Though consideration of the problem of the shell-shock pensioner may not have been directly included in the reference to the Committee, yet we could have wished that an opinion on this thorny subject had been expressed.

We may hope that the recommendations of the Committee on prevention and treatment will be carefully studied and will become a part of the special education of officers in the navy and army, both medical and executive. It is to be desired, also, that in the deplorable event of another struggle between the nations the inevitable problem of the future pensioner may be borne in mind by recruiting authorities, and every care taken to avoid the reappearance of the difficult problem with which the nation is now confronted.

THE CALCUTTA SCHOOL OF TROPICAL MEDICINE, 1921.

UNDER the endowments given by the Indian Tea, Jute, and Mining Associations (at the suggestion of Sir Leonard Rogers) for the investigation of diseases affecting the health of their labour forces important researches have been carried out at the Calcutta School of Tropical Medicine, and are briefly recorded in the report for 1921 which has recently been issued. Dr. L. E. Napier, who has been investigating kala-azar, which is still affecting some tea estates in Assam, has attempted to infect animals and to transfer the infection from one to another by biting insects, but so far without much success. He succeeded in infecting two monkeys (*Macacus rhesus*) by intravenous injection of 10 c.cm. of an emulsion of a kala-azar spleen; they developed only a very mild infection, which produced no symptoms and disappeared within a few months; it is not surprising therefore that the insect-carrying experiments gave negative results. Much work has also been done at diagnostic blood tests for kala-azar, the globulin precipitation test and the hæmolytic test proving of no practical value. On the other hand, a new aldehydic test described by Napier has furnished valuable results: 1 c.cm. of the serum of the patient is placed in a small test tube, and one drop of commercial formalin is added; if the case be one of kala-azar the serum becomes solid and opaque like the white of a hard-boiled egg in from three minutes to two hours; 88 of 90 kala-azar cases verified by spleen puncture gave positive results, while only 1 of 60 cases negative on spleen puncture was positive to the test. Much work has also been done on the treatment of the disease by antimony salts, and

an important advance has been made in the discovery that a 2 per cent. solution of a chemically pure scale preparation of sodium antimony tartrate can be injected intramuscularly with only slight temporary pain and no inflammatory reaction. Five cases in children, all under the age of 7, in whom repeated intravenous injections are very difficult, have been cured by this method. If on further experience the plan proves feasible on a large scale, it will make it much more easy to stamp the disease out of infected districts than is the case at present. Dr. J. B. McVail, in his report on the work of the hookworm research laboratory, deals first with the finding of ankylostoma eggs in stools; for this purpose Lane's levitation method gave the best results, although a simpler plan, requiring less apparatus, has been worked out in the laboratory and adopted for routine work. About half a gram of emulsified stool is allowed to stand for ten minutes on a slide between grease pencil marks; it is then gently immersed in water to float off the debris and examined under the microscope; in this way even mild cases can be quickly diagnosed by finding the ova. The effect of various conditions and chemicals on cultures of the larvae has been tested; a temperature of 90° to 96° F. prevented all development, but the septic tank, even with 1 in 400 chlorinated disinfectant, failed to do so; wet sand seven inches thick was traversed by active larvae in a week. They can penetrate wet clothing and even wet shoe-leather, although boiled linseed oil will protect the latter against them. Methods of treatment have been tested to find the most suitable plan for dealing with a large, apparently healthy, labouring population as out-patients. It was found that three treatments, at seven to ten days' intervals, with 30 minims in three equal doses at hourly intervals, commencing one hour after a meal without any preliminary purge, removed 98.2 per cent. of the worms; the sample was previously tested to ensure that it was non-toxic. The wholesale cost of the full course is 4d. per patient. The plan should make it possible greatly to improve the health and working powers of labourers in Lower Bengal, where 80 per cent. are infected. Both inquiries were handicapped during 1921 because the Carmichael Hospital for Tropical Diseases was not opened until December. Much good work was, however, accomplished, and the progress of this important experiment in the endowment of medical research in the tropics by the large employers of indigenous labour must be pronounced to be very encouraging.

THE MAUDSLEY HOSPITAL.

The renovation of the Maudsley Hospital after its service as a military hospital during the war and subsequently as a neurological centre under the Ministry of Pensions has now been completed, and the hospital is equipped for its original purposes—namely, the early treatment of cases of acute mental disorder, the promotion of exact scientific research into the causes and pathology of insanity, and the clinical instruction of medical students. At its last meeting before its summer recess the London County Council decided that, at any rate at the beginning of its work, the hospital shall be entirely dissociated from certified lunacy. Cases under certificate are not at present to be received, and if possible there is to be no certification in the hospital either for retention or transfer. This will involve making arrangements for speedy removal by relatives accepting responsibility, and possibly arrangements with Poor Law authorities when this responsibility is not discharged. This will mean the exclusion of some cases of the most suitable class for teaching and for treatment to recovery, and until legislation is introduced to provide for the reception without certification of certifiable cases, the work of the hospital will be seriously hampered. The Council has decided to make representations to the Government that such legislation should be hastened. The Maudsley Hospital has in-patient accommodation for 157 persons. One ward on each side of the hospital is set aside for acute cases. The staff will consist of the medical superintendent (Dr. E. Mapother), a deputy medical superintendent, a senior assistant medical officer, and two assistant medical officers. The remuneration of these four members of

the assistant medical staff will be respectively £650, £450, £350, and £300 on pro-war economic conditions, and for one of the junior appointments women candidates will be eligible. No definite proposal has been submitted with regard to clinical assistants; it is thought that they may be obtained without payment when the hospital is in being, but they will be engaged so as to afford them opportunity for the study of psychological medicine, and not with a view to avoiding the appointment of necessary staff. The medical superintendent proposes that junior assistant medical officers of the London mental hospital service should be seconded for service at Maudsley Hospital as part of the course for the diploma in psychological medicine. The appointment of assistant medical officers will be subject to review at the end of each year of service. The services of certain consultants will be retained, and for these and for dental services a sum of £500 a year will be provided. The nursing staff will consist of a matron, assistant matron, seven sisters, 18 female staff nurses, 23 female probationer nurses, and 12 male probationer nurses. Cases will be admitted principally through an out-patient department and through Poor Law institutions, the medical officers of which will be asked to notify what appear to be suitable cases with a view to such cases being interviewed by one of the hospital medical staff; another source of admission will be cases seen privately. The out-patient department is to be opened, if possible, in advance of the wards; the letter of a doctor or similar recommendation will be required, except in the case of an ex-patient of a London county mental hospital. Patients in a position to do so will pay a moderate sum. Facilities will be given for the admission of poor people, so that there may be no suggestion that the hospital is reserved chiefly for paying patients. The cost of maintenance of the whole hospital, with the full complement of staff and patients, will be £37,500 a year, but it is expected that part of this will be recouped by patients' payments. It has been arranged to retain the services of Sir Frederick Mott, who was due to retire on October 23rd, until March 31st, 1923, so that the Council may have the advantage of his advice in connexion with the scheme for the administration of the Maudsley Hospital. After March 31st his services are to be retained for a further six months in an advisory capacity at a remuneration to be determined.

A CENTENARY OF SIR CHRISTOPHER WREN.

SIR CHRISTOPHER WREN (1632-1723) has for the medical profession a double interest—general and special—over and above that which every educated man must have for his outstanding genius. In the first place, early in his life, before he entered as an undergraduate at Oxford, he assisted Sir Charles Scarborough, physician and mathematician, in making and demonstrating anatomical preparations and in various experiments for his anatomical lectures at Surgeons' Hall. Wren, like his early master, was one of the original Fellows of the Royal Society—in fact, his rooms at Gresham College, where he was Professor of Astronomy, served as a meeting place for those who subsequently founded the Royal Society. Another point of general medical interest is that when 21 years old Wren executed a number of elaborate drawings which appeared in Thomas Willis's famous "*Cerebri Anatome Nervorumque Descriptio et Usus*" (1664). The special and somewhat restricted point of interest to the medical profession is that Wren was the architect of the third home of the Royal College of Physicians of London, that in Warwick Lane, Newgate Street (1672-1825), with its fine theatre erected at the expense of Sir John Cutler, a City merchant, who was an example of that not unknown combination of "petty personal parsimony" and large benevolence and public spirit. This theatre Cutlerianum was described in James Elmes's memoir of Sir Christopher Wren as "a perfect study of acoustical and optical architecture," an example, it may be added, that might be more constantly imitated in some modern buildings. Sir Christopher Wren died on February 25th, 1723, and accordingly the Royal Institute of British Architects is making arrangements for a commemoration week beginning on Monday, February 26th

next. It has formed a "grand committee," on which, it is hoped, representatives of appropriate Government departments, the great artistic, scientific, and archaeological societies, and the universities will serve. It is therefore fitting that the medical profession should take part in this bicentennial commemoration, and at the request of the Royal Institute of British Architects the Royal College of Physicians recently appointed Dr. R. Dawtrey Drewitt as its representative on the grand committee. It is proposed to organize a procession from the Mansion House to St. Paul's Cathedral, where a memorial service will be held and a visit made to the crypt, when the President of the Royal Institute of British Architects will lay a wreath on Wren's tomb. There are, it may be mentioned, two other memorials in the cathedral to its great architect, one being the well-known inscription over the door of the north transept, which directs the visitor who desires to see a memorial to Wren to look around. On the evening of this day a meeting of the Royal Institute of British Architects will be held for the reading of papers on the life and work of Wren, and an exhibition of his drawings, manuscripts, and relics will be on view for several days at the house of the Institute in Conduit Street. A pageant illustrating his times is to be arranged, and visits are to be paid to the buildings erected under his direction.

THE FATAL CASES OF FOOD POISONING AT LOCH MAREE.

PUBLIC attention has been very forcibly directed to the subject of food poisoning by the tragic occurrences last week in an hotel at Loch Maree, (Gairloch, remotely situated in Ross-shire, where eight persons have died with symptoms suggestive of botulism. According to the information at present available the facts seem to be as follows: On Monday, August 14th, a number of persons staying in the hotel started on fishing or walking expeditions and took sandwiches with them. Some of these sandwiches were made with meat paste, and it appears that only those who consumed these potted meat sandwiches suffered. The sandwiches were eaten for lunch on August 14th by eight persons, and the earliest symptom, diplopia, was observed in one of them before breakfast on August 15th, so that the shortest interval between ingestion of the sandwiches and the development of the earliest symptom was about eighteen hours. The seven other persons affected began to suffer during the course of August 15th; two, both of them ladies, died on that day; the others were men—two died on August 16th, two on August 17th, and two on August 21st. In addition to diplopia, which seems in all instances to have been the first noticed, the symptoms mentioned are ptosis, dizziness, paralysis and feeling of constriction of the throat, vomiting and collapse. Vomiting, however, does not appear to have been a marked feature, and no mention is made of diarrhoea. These symptoms do not resemble those of food poisoning due to one or other of the members of the Gaertner group of bacilli, but are like those produced by *B. botulinus*, an anaerobic organism which causes the disease known as botulism. This name was given to the disease in Germany, where the first cases were observed, because they were traced to the eating of certain sausages (*botulus*, a sausage). A few years ago Dickson, in a report to the Rockefeller Institute for Medical Research,¹ stated that *B. botulinus* could exist in material not containing any animal protein; he detected it in canned vegetables and fruit. Cases have been reported within recent years in California, where the disease was thought to be due to the eating of olives, or french beans, preserved in cans or bottles. In an outbreak in Idaho, mentioned not long ago in our columns (June 3rd, 1922, p. 893), six persons died after eating greases which had been canned ad homo. The early symptoms in these cases included dizziness, blurring of vision, and unsteady gait, followed by vomiting; later, blepharoptosis, paraesthesia of the extremities, weakness of the arm, leg, and especially neck muscles, dyspnoea, dysphagia, and aphonia were noted.

Dilatation of the pupils was observed and was accompanied by sluggishness of the light reflex; Babinski's sign was present, and the knee-jerks were exaggerated. The organism which causes botulism is destroyed by boiling. It has been isolated and an antitoxin has been prepared, but so far little benefit appears to have been derived from its administration in man, although animal experiments have encouraged perseverance in its use. So far as we can ascertain no other form of treatment has been proved to be of any avail in botulism. In the north of Scotland a fatal disease has recently occurred among horses, and it has been stated that the symptoms resemble those of botulism. Fortunately, portions of the suspected meat paste have been secured. It is stated to have been supplied originally by a large firm of manufacturers, and it is possible that the infection arose locally in some way as yet unexplained. As soon as the fact that an outbreak of food poisoning had occurred became known the Scottish Board of Health dispatched medical officers to the spot, and Dr. Dittmar, one of its medical inspectors, was able to obtain first-hand information from medical men on the spot, among whom were included several visitors on holiday in the neighbourhood. A public inquiry will no doubt be held, although the exact form it will take had not been settled on August 22nd. The Lord Advocate has power under the Scottish Accident and Sudden Death Enquiry Act to order a public inquiry into any case of sudden or suspicious death in Scotland. The Scottish Board of Health would also have power to hold a public inquiry; whatever the final decision on this point may be, there can be little doubt that the most important evidence will be with regard to the results of the bacteriological inquiries now being carried out. The outbreak was first reported in the lay press as "ptomaine poisoning," a term which had its origin in a theory soon proved to be erroneous, and long ago abandoned by the medical profession. Outbreaks of food poisoning are due to infection. If the outbreak is one of botulism, it is, we believe, the first that has occurred in Great Britain.

MEDICAL SCIENCE IN NEW ZEALAND.

In the *Proceedings of the University of Otago Medical School*¹ for 1922 there have been collected in one volume some fourteen recent articles by members of the school, first published chiefly in the *New Zealand Medical Journal* and the *Transactions of the New Zealand Institute*. They cover a wide field, and show that a high standard of scientific research and clinical work is being attained in Dunedin. The editor of the volume, Dr. D. W. Carmalt Jones, who is professor of systematic medicine in the University, contributes an interesting article on the meaning of the word "symptom," and also shorter notes on amoebic dysentery, on two cases of peripheral neuritis, on syphilis of the nervous system, and (with Mr. J. Renfrew White) on two cases of laminectomy. Professor W. P. Gowland writes on the surgical anatomy of the thyroid gland, Dr. J. W. Hall on diabetes mellitus, Professor L. E. Barnett on hydatid thrill, Dr. A. P. Marshall on the selection of an anaesthetic, and Professor A. M. Drennan on aneurysms of the larger cerebral vessels. Dr. A. J. Hall and Dr. E. H. Williams contribute short notes on cystic disease of the accessory sinuses and on diaphragmatic hernia respectively. The physiological action of tutin—the active principle of the tutu plant, which has had an unenviable notoriety in New Zealand as a poisoner of sheep and cattle from the days of the earliest settlers—is reviewed by Dr. Frank Fitchett and Dr. John Malcolm, and Mrs. Dorothy E. Johnson examines the food values of New Zealand fish. The fact that the numbering of the pages of each reprint is independent will cause some difficulty to those who may wish to quote the articles, and this defect should, if possible, be remedied in any future issues of the *Proceedings*. Professor Carmalt Jones and the University of Otago are to be commended for their enterprise and their achievement.

THE JUNIOR RED CROSS.

THE July issue of the *World's Health*, a monthly magazine issued from Geneva by the League of Red Cross Societies, is devoted mainly to an exposition of the history and organization of the Junior Red Cross and to advocacy of its international extension. Its objects are to inculcate in the children of the country where the movement is adopted "the ideal and practice of service, especially in relation to their own health and that of others, the understanding and acceptance of civil responsibility, and the cultivation and maintenance of a spirit of friendly helpfulness to children in all countries." The basic purposes of the League of Red Cross Societies itself are "the improvement of health, the prevention of disease, and the mitigation of suffering throughout the world, and to secure co-operation for these purposes." Naturally it will occur to the reader to ask what may be the relation of this excellent scheme to the Boy Scout and Girl Guide movement, and it is satisfactory to learn that the Junior Red Cross is believed to make for solidarity among all the organizations of Youth. In various countries groups like Boy Scouts have found Red Cross aims entirely in accord with their own. In the United States membership of the Junior Red Cross is regarded as part of the training for citizenship and helps to recruit adult members for the Red Cross. Teachers play an important part in the Junior Red Cross. Many of them have found it an ideal instrument for influencing the young generation aright. A specimen plan of organization is given, but it is a principle of the whole scheme that in different countries divergences of method are not only necessary but desirable, as every variety of experiment has its value. The cost of junior membership may often at first have to be met by the national organization concerned, but the real benefits of it are obtained when the juniors have become adults. Also it is a humanitarian work for which the resources of a national Red Cross Society may be considered available, though it is better that at least part of the administrative costs should be borne by the juniors themselves. Members may be enrolled either by classes or by groups. Overlapping with other organizations being avoided, the scheme has every appearance of being a valuable addition to the voluntary agencies which do so much to supplement the activities of public departments, whether State or rate supported.

ANIMAL EXPERIMENTS IN 1921.

THE annual return showing the number and nature of experiments on living animals during the year 1921¹ gives a list of all "registered places" where such experiments may be performed, the names of all persons who hold licences during 1921, together with the registered place for which the licence was in force and the number and nature of experiments performed. In the year 1921 twenty new places were registered for the performance of experiments and thirteen places were removed from the register. The total number of licensees was 812, of whom 219 performed no experiments. The experiments may be divided into two main groups, according to whether or not an anaesthetic was used. It should be noted that the granting of a licence only permits the licensee to perform experiments under an anaesthetic, for the law declares "the animal must, during the whole of the experiment, be under the influence of some anaesthetic of sufficient power to prevent the animal feeling pain; and the animal must, if the pain is likely to continue after the effect of the anaesthetic has ceased, or if any serious injury has been inflicted on the animal, be killed before it recovers from the influence of the anaesthetic which has been administered." To perform other experiments or even to observe the subsequent course of experiments undertaken with an anaesthetic the licensee must be possessed of special certificates. Special certificates are also necessary for experiments on dogs, cats, horses, asses, mules, and other large animals. The total number of experiments with anaesthetics was 8,165, and of

these 2,053 were simple inoculations into the skin of guinea-pigs, which were anaesthetized in order to keep the animals motionless during the introduction of a minute quantity of the fluid to be tested for the purpose of standardization. Of the remaining 6,112 experiments, comprising all the cases in which any serious operation was involved, 2,751 were performed under the licence alone, and were subject therefore to the restrictions above mentioned. In all operations, with the exception of a few special cases dealing with the efficiency of antiseptics, the law demands that the operation shall be performed antiseptically so that the healing of wounds shall, as far as possible, take place without pain. If the antiseptic precautions fail, and suppuration occurs, the animal must be killed. The following "pain condition" is attached to the licence under special certificates: "If an animal, after and by reason of the said experiments, is found to be suffering pain which is either severe or is likely to endure, and if the main result of the experiment has been attained, the animal shall forthwith be painlessly killed. If an animal, after and by reason of the said experiments, is found to be suffering severe pain which is likely to endure, such animal shall forthwith be painlessly killed, whether the main result of the experiment has been attained or not. If any animal appears to an inspector to be suffering considerable pain, and if the inspector directs such animal to be destroyed, it shall forthwith be painlessly killed." The total number of experiments without anaesthetics was 67,097. These were mostly simple inoculations and hypodermic injections, but included also some feeding experiments and administration of various substances by the mouth or by inhalation or by external application, and the abstraction of blood by puncture or simple venesection. In no instance was a certificate dispensing with the use of anaesthetics allowed for an experiment involving a serious operation. The total number of experiments was 75,262, being 4,895 more than in 1920. The objects for which these experiments were performed were very diverse. A large number, almost wholly simple inoculations, were performed either on behalf of official bodies, with a view to the preservation of the public health or directly for the diagnosis and treatment of disease. Experiments conducted at a sewage farm to test the character of the effluent by its effect on the health of fish is an example of work carried out for the preservation of public health. Nearly 20,000 experiments were performed for the preparation and testing of antitoxin serums and vaccines and for the testing and standardizing of drugs. The several registered places were visited frequently by the inspectors, usually without previous notice, and they report that the animals were suitably lodged and well cared for, and the licensees generally attentive to the requirements of the Act and the conditions attached to their licences.

MAN'S INSECT ENEMIES.

WE have received a copy of an address entitled *Man's Insect Enemies* which was delivered last May to the undergraduates of the University of Hong-Kong by Dr. Francis Clark of London, formerly professor of medical jurisprudence and dean of the Faculty of Medicine. Dr. Clark pointed out that while the treatment of disease was a matter solely for trained physicians and surgeons, the prevention or avoidance of disease vitally concerned the whole community, and was worthy of study by everyone. He went on to deal with the more important diseases conveyed by the agency of insects. In regard to bubonic plague, he outlined the best methods of controlling the rat population, the only safe way of doing so being by reducing to a minimum their food supply by efficient scavenging, combined with the rat-proofing of buildings. He told his audience that it was in 1894, when working in Hong-Kong, that Manson suggested that the parasites of malaria, then recently discovered by Laveran, were carried by mosquitos; the truth of this was later conclusively established by Ronald Ross. Dr. Clark mentioned that in a recently published interview, Sir

¹ *Experiments on Living Animals*. Return for 1921. London: H.M. Stationery Office (to be obtained through any bookseller), price 1s.

Ronald Ross stated that the best work which was being done in the practical prevention of malaria had been accomplished at Kharoon, at Klang (F.M.S.), and at Hong-Kong. Turning next to yellow fever, Dr. Clark observed that the spirochaete which caused it was also conveyed by a mosquito, which bred chiefly in collections of water around houses; on this account it was important not to place the legs of the household ice chest in cups of water, as was frequently done in the tropics to prevent the access of ants to the food, but to fill the cups with kerosene. He brought a serious indictment against the common house-fly as a carrier of the infection of typhoid fever, dysentery, enteric, occasionally of cholera, and probably of several other diseases. Flies were largely responsible, he said, for the spread of the various forms of ophthalmia from man to man in tropical regions. They were agents, also, in the propagation of hookworm disease, as it was found that when fly eggs which had been laid in polluted earth developed into larvae they churned up and aerated the soil so that the hookworm eggs hatched out more readily. Dr. Clark had high hopes of the efficacy of carbon tetrachloride for the treatment of hookworm disease, as recent information from Fiji was to the effect that even a single dose might free the victim of 98 per cent. of the parasites. This treatment was due to a suggestion made last year by Hall, a veterinary surgeon of Washington. The methods of infection in filariasis, relapsing fever, trench fever, typhus fever, and sleeping sickness were in turn described, and preventive methods were outlined. In regard to infantile paralysis Dr. Clark said that some light had been thrown on the subject by the recent research work of certain American veterinary surgeons, for it had been shown that wry-neck, a fatal paralytic disease in poultry, was caused by an infection conveyed by a certain small fly which occurs all over the world. This suggested that infantile paralysis might be disseminated in a similar manner.

ASSOCIATION OF CERTIFYING FACTORY SURGEONS.

The excellent work the Association of Certifying Factory Surgeons does for its members is well exemplified in the Annual Report for 1921, which has recently been issued. The Home Office recognizes this Association as representative of factory surgeons, as is shown by the account given of the negotiations with the Factory Department that resulted in a complete revision of the part of the Home Office Annual Report which deals with the examinations for certificates of fitness. Particulars are given also of a joint conference between the Chief Inspector and the Secretaries of the British Medical Association and of the Factory Surgeons' Association on the matter of fees and the necessity for medical supervision of first-aid arrangements in factories. In these circumstances it seems regrettable that the more recently appointed surgeons are not taking the trouble to become members. The report for 1921 should be sufficient to convince any factory surgeon that he will be well advised to join this special organization. The part of the report dealing with the "Future of the certifying surgeon" is very much to the point. The first paragraph definitely lays down that the only way to deal with the great amount of industrial sickness and mortality is by abolishing the unhygienic conditions of occupation, that it is an obligation on the Government to create the necessary medical supervision in the factories themselves in order to ascertain the faults and devise the remedies, and that the certifying surgeon could be made into a useful adjunct in carrying out a workable scheme. It is claimed that industrial preventive medicine is a branch of State medicine and must be taken in hand by the State if it is to prove universally effective; in support of this contention it is pointed out that the remarkable results following the introduction of the medical element into the study of specific dangerous trades were not attained without establishing statutory notifications and regulations, aided by a large amount of valuable work done by the certifying surgeon. It is considered logical to infer that machinery and methods similar to those mentioned could be utilized to prevent certain general diseases

which now single out particular industries and produce heavy mortality. At the same time it is recognized that financial reasons will prevent the discharge of any State obligation in this direction for some considerable time to come. It is therefore suggested that the correct policy of the certifying surgeon is to make himself acquainted with such voluntary efforts as are being made to improve the hygienic conditions of factory employment. The certifying surgeon should carefully consider the practicability of undertaking by private arrangement, particularly in factories which he is already visiting at regular intervals, a considerable portion of what may be regarded as the essential medical supervision. The report also points out the wisdom of co-operation with welfare supervisors, and how each can render assistance to the other to the advantage of both. We are informed that any person interested can obtain a copy of the report on applying to the secretary at 40, Brazennose Street, Manchester.

NAVAL MEDICAL SERVICE MEMORIAL.

A MEMORIAL tablet to over two hundred naval medical officers and members of the nursing staff who were killed or died on active service during the war was unveiled on August 17th by Sir Robert Hill, Medical Director-General, R.N. The ceremony was attended by many relatives of the fallen and by a number of medical officers. Sir Robert Hill said he could conceive no more suitable spot in which to place the tablet than in the gateway of Haslar Royal Hospital, built in the eighteenth century, and itself a memorial to the most glorious days of English history. To Haslar Hospital were brought the sick and wounded from the battles of Copenhagen, St. Vincent, the Nile, Trafalgar, the Crimea, and the Baltic; during the great war it was filled to overflowing. Through its gateway passed every probationer surgeon, and future generations would pay their tribute to the sacrifices of their brother officers and the nursing sisters who gave their all for King and country, and left for ever an example of patriotism. Similar memorials are to be erected at Chatham and Devonport.

THE EDUCATIONAL NUMBER, 1922.

OUR next issue will be the annual Educational Number of the BRITISH MEDICAL JOURNAL. As briefly indicated last week, the usual features will be supplemented by an important introductory article on the training of the medical student, written at our request by Sir Clifford Allbutt; a note by Professor W. E. Dixon on the future of pharmacology and its place in the curriculum; a full account of the forthcoming changes in the scheme of study and examination prescribed by the new resolutions and recommendations of the General Medical Council; and a short statement of the numbers of the medical profession year by year during the past forty-five years. The customary sections, giving a summary of the requirements of the universities and other licensing bodies in Great Britain and Ireland, have been brought up to date, and the information showing the opportunities offered by the various medical schools and teaching institutions has been corrected by the authorities concerned. The Educational Number will include also articles on the public services and the medical education of women to-day, and on post-graduate study; and on some general aspects of professional study and the practice of medicine, addressed mainly to prospective students and their parents.

ITALY is taking measures to ratify the conventions of the International Labour Conference of the League of Nations with regard to women. As soon as compulsory insurance against sickness has been established all women will be entitled to six weeks' rest before the probable date of childbirth, and the provision will apply to women employed in commercial undertakings. Maternity insurance, which will affect these women, and also those employed in minor industries, will provide grants for six weeks before and six weeks after childbirth, as well as free attendance by a doctor and midwife. A bill is to be introduced to make the Italian law with regard to the employment of women and young persons at night conform with the terms of the convention.

Nova et Vetera.

BUCCANEER SURGEONS.

In giving an account some months ago (February 18th, 1922, p. 289) of the career of Thomas Dover, buccaneer and inventor of the powder which bears his name, it was said that he rescued Alexander Selkirk, the skin-clad hero of *Robinson Crusoe*, who had been marooned on the island of Juan Fernandez. Probably, however, the credit should be given to William Dampier, who had known Selkirk long before, and, moreover, was well acquainted with the island, which he calls John Fernando's.

More than a quarter of a century earlier Dampier had taken part in the great buccaneering expedition across the Isthmus of Panama to the South Sea and after various excursions and adventures had been one of the party which returned on foot to the Caribbean Sea. Wherever he was and despite all difficulties this remarkable man seems to have kept a journal in which he noted not only daily events but descriptions of the manners and customs of the natives, of the flora and fauna, the weather and the chief physical features of the country. In his descriptions of the voyages of the buccaneers (or privateers, as they preferred to call themselves) there are frequent references to the surgeons, which show how much their services were valued. Thus Dampier states that on one occasion a ship's company refused to put to sea because they had no surgeon; and when "our Surgeon, Mr. Wafer," was injured "we allowed him a slave to carry his things, being all of us too more concerned at the accident, because liable ourselves every moment to misfortune and none to look after us but him."

When the buccaneers landed to attack a town the surgeons accompanied them, and it is recorded by Dampier that in an attack on an Indian town in Mexico "our surgeon and one man more were wounded with arrows." In the disastrous attack on Arica in 1680 the surgeons had occupied a church as a hospital, where they found a store of wine. Possibly this discovery accounts for the fact that they were left behind when their comrades retreated. They were, however, released by the Spaniards on their consenting to settle down to practice in the city.

In the reign of Charles II the professional education of the average practitioner in England probably consisted almost entirely of the acquirement of precepts and experience in the service of a master under the apprenticeship system. Theoretical knowledge was at a discount. Anatomy, physiology, and chemistry were then far outside the ordinary curriculum, and even seventy years later, when the practice of surgery had made great advances, Roderick Random's master is represented as preferring the knowledge of "how to bleed and give a clyster, spread a plaster and prepare a potion," to that of the causes of muscular action and the mystery of the brain and nerves.

The surgeons of the buccaneers probably worked by rule of thumb and gained their knowledge not from books, but from their masters and their own hard-won experience. The crews were probably less liable to scurvy than those of less law-abiding vessels, for they relied for food largely on such fish and turtles as they could catch, and were frequently ashore, where they got fresh vegetables and cattle. The beef they did not eat fresh they smoked and stored on board, and the name of buccaneer is said to be derived from a Brazilian word signifying "smoked meat." Yet they were not immune from scurvy, for Dampier tells us that—

"At John Fernando's our sick men were ashore all the time" (sixteen days) "and one of Captain Eaton's Doctors (for he had four in his Ship) tending and feeding them with Goat and several Herbs, whereof here is plenty growing in the Brooks: and their diseases were chiefly Scorbutick."

No wonder it was thought worthy of record that in a certain prize they took seven or eight tuns of marmalade of quinces, for marmeloes or quinces had been recommended fifty years earlier by Captain John Smith in his *Accidence, or the pathway to experience necessary to all Young Seamen*.

One of the buccaneer surgeons, the Lionel Wafer above mentioned, left an account of his experiences in *A New Voyage and Description of the Isthmus of America*, London, printed by James Knapton, at the Crown, in St. Paul's Churchyard, 1699. It is not known where he was born, but he appears to have been an Englishman with some knowledge of Scotland and Ireland. His first voyage, "being then very

young," was made "in the Service of the Surgeon of the Ship" to the Strait of Malacca in 1677. Two years later he went in a similar capacity to Jamaica, where for some time he practised surgery, but falling in with two privateering captains there he was tempted to try his fortune with the buccaneers, and after some adventures on the Atlantic coast of Central America he crossed the isthmus with Dampier and others under the command of Captain Bartholomew Sharp. In the Pacific he went as far as Juan Fernandez and Drake's Island, but after various adventures on sea and on shore he and Dampier joined the party of some fifty men who were dissatisfied with Sharp's leadership, and in a ship's longboat and native canoes started to return to the isthmus and recross it on foot to the Caribbean Sea. On the fifth day of the journey Wafer was disabled. The accident is best described in his own words:

"I was sitting on the ground near one of our Men, who was drying of Gunpowder in a Silver Plate. But not managing it as he should, it blew up and scorched my Knee to that degree, that the Bone was left bare, the flesh being torn away, and my Thigh burnt for a great way above it. I applied to it as I had in my Knapsack: And being my Companions, I made hard shift to pany for a few days; during which our slaves ran away from us and among them a Negro whom the Company had allowed me for my particular Attendant, to carry my Medicines. He took them away with him, together with the rest of my Things, and thereby left me deprived of wherewithal to dress my Sore; inasmuch that my pain increasing upon me, and being not able to trudge it further through Rivers and Woods, I took leave of my Company, and set up my Rest among the Darien Indians."

To this accident we owe the interesting account of the Indians which Wafer has given. At first he and his four companions were objects of some suspicion at the Indian settlement and were rather roughly treated, although, as he says, "Not that they were naturally inclin'd to use us thus roughly, for they are generally a kind and free-hearted people." When, however, the natives heard of the good treatment which some of their fellows had received from Dampier and his party they became kind and hospitable. The Darien Indians seem to have been generally well disposed towards the English, partly because they hated the Spaniards, with whom the buccaneers waged war, and partly because, as it seems, the English had the good sense—perhaps the humanity—to treat them well. Had the natives been hostile travelling by land would have been made more difficult than it was, if not quite impracticable.

Wafer seems to have been much impressed by the presence of albinos among the Indians; their numbers he estimated at one to every two or three hundred of the population. He seems to have been quite ignorant of the existence of albinism in Europe, and of course does not use this term, but he quite accurately describes it, including the visual troubles which are incident to it, and he realized that the albinos were not a separate race. Much as he liked the Indians, he did not extend his affection to their arboreal cousins, the monkeys of the isthmus, who, he says, are—

"a very waggish kind of Monkey, and played a thousand antic Tricks as we march'd at any time through the Woods, skipping from Bough to Bough, with the young ones hanging at the old ones' Back, making Faces at us, chattering, and if they had opportunity, pissing down purposely on our Heads."

The buccaneers found the monkeys very good eating and taught the Indians to overcome their repugnance to this kind of meat.

One of Wafer's party was a Mr. Richard Gopson, who had served an apprenticeship to a druggist in London. This bold buccaneer carried with him a copy of the Greek Testament; he occupied his leisure in its study, and would read aloud in English to anyone who cared to listen. Gopson is an instance of the heterogeneous composition of a privateer's crew, to which Dampier alludes when he says that one ship's company comprised skilled artisans in every craft, so that they were capable of all sorts of constructive work as well as of the wanton destruction with which the buccaneers are generally credited.

No doubt many of them were not criminally inclined, but took to the life from sheer love of adventure, tinged with the hope of gain. Their life was hard at sea, and no less hard when travelling on the isthmus carrying all their belongings on their backs. Crossing a river in flood, loaded with a heavy musket, ammunition, and three or four hundred pieces of eight (or dollars), was no child's play, and at least one of them owed his death to his load of silver, which must alone have weighed more than twenty pounds.

His dressings and drugs being lost, Wafer submitted to an

Indian method of cure, which consisted in the application of poultices of chewed herbs of unknown origin; in this way he was cured in twenty days, except for a persistent weakness and numbness. Native surgical methods seem to have been less simple, for Wafer gives the following account of the way in which a patient was bled:

"The Patient is sorted on a Stone in the River, and one with a small Bow shoots little Arrows into the naked Body of the Patient, up and down; shooting them as fast as he can and not missing any part. But the Arrows are gaged, so that they penetrate no further than we generally thrust our Lancets: And if by chance they hit a vein which is full of Wind, and the Blood spurts out a little, they will leap and skip about, showing many Antick Gestures, by way of rejoicing and triumph."

A similar method has survived in New Guinea up to the present time for opening abscesses. Specimens of the bows and arrows employed are to be seen in the Wellcome Historical Museum, 54A, Wigmore Street, London.

There is a quaint illustration in the original book showing this operation. It having been decided that one of the wives of Laeenta, the Indian king, should be bled in this manner, Wafer persuaded the king to allow him to bleed from a vein in the usual way. Alarmed by the sudden gush of blood, the Indian at first threatened to take the operator's life, but when the arm was bound up and the patient happily recovered he was delighted with his new Court surgeon. Just as Dr. Gabriel Boughton is said to have gained the confidence of the Emperor of Delhi and his viceroy by his successful treatment of their womankind, so on a much smaller scene did Wafer gain the confidence of the King of the Darien Indians, to the no small advantage of himself and his companions. So successful was he that the king could not for a long time be persuaded to part with him, but kept him about his person, offered him his daughter in marriage (as soon as she should be old enough), and took him with him on all his expeditions. Wafer "lived in great Splendour and Repute," and adopted the Indian full-dress of a coat of paint, a gold nose-plate clipped on to the septum nasi and hanging down over the upper lip, and a funnel or horn concealing the penis, but leaving the scrotum exposed. The painting was done by the women, usually by tattooing; to this Wafer would not submit, but he had the colours laid on in little specks, "red, yellow, and blue, very bright and lovely."

Laeenta was at length persuaded to part with the Englishmen on a plausible pretext and sent them to the north coast, where they found Dampier and his friends with a vessel, which they had acquired in the usual way. (Convoy, the wise it call!) The journey across swollen torrents and a lofty mountain range was difficult, and in traversing the mountains the Europeans seem to have suffered from the rarity of the air.

Wafer had been some hours on board ship in his coat of paint and his nose-piece before he was recognized with the joyful shout of "Why, it's our doctor!" He says that a month elapsed before all the paint had worn off.

For six years more he was with the buccaners: in Virginia, on the Guinea coast, and round Capo Horn to the Philippines, and then back to London. Besides the account of his life among the Indians his book includes descriptions of the country and its products, and of his adventures in the South Sea, but these are of little interest compared with those of Dampier, and it is to be remembered that, as he says, he kept no journal, whereas Dampier made notes of his observations at the time. No doubt Wafer was induced to publish his book by the interest excited at home by Paterson's disastrous attempt to colonize Darien. The main facts of his story are corroborated by Dampier, and there seems no reason to doubt his substantial accuracy.

With the advent of peace between France and Spain and a better understanding between Great Britain and that country, the buccaners' occupation soon became too hazardous. The more desperate characters among them became pirates of the indiscriminating and uncompromising type with which writers of fiction have made us familiar, many of whom ended their careers at Execution Dock, instead of, like Wafer and R. L. Stevenson's Industrious Pirate, "retiring and being respected by his neighbours."

As for Dampier, he became a recognized authority on geography, oceanography, and meteorology, and as such was consulted by the Government, and was given the command of a king's ship with which to explore New Guinea and Australia, where he gave his name to Dampier's Straits, but accomplished little else of note.

England and Wales.

LONDON'S WATER SUPPLY.

SIR ALEXANDER Houstoun's report to the Metropolitan Water Board for the year ending March 31st, 1922, shows that by that time the acute anxieties caused by the great drought of 1921 had been much allayed by the rains of the early months of this year. In a note on the subject in our issue of June 24th we ventured to hint that a change of weather might come in time to replenish London's sources of supply, and this is what happened. But the peril escaped is not being forgotten, and the problem of how to provide against future dangers is occupying the mind of the authorities. It is now some thirty years since Lord Balfour of Burleigh's Committee considered the great scheme for settling once for all London's difficulties by impounding a practically inexhaustible supply from the mountains of Wales, and leading it across England to the metropolitan area. The cost would have been enormous, and in spite of the weighty considerations urged in its favour the scheme was rejected. Fato has been kind to the tribunal which reached that momentous decision. Enteric fever, which was then almost endemic in this country, has very greatly diminished, and London's present water supply cannot be charged with having been the means of conveying that or any other of the water-borne diseases to the inhabitants. The double principle of prevention of pollution at the sources of supply; and purification after capture, has been wonderfully successful. Yet the possibility of a breakdown cannot be ignored, and Sir Alexander Houstoun urges now, as in former reports, the risks of an accident and the need for ceaseless watchfulness.

"If the true history of all past water epidemics could be learnt," he says, "in nearly all cases something in the nature of an accidental circumstance would be found to be the explanation. Further, in many cases, it is to be feared it would be true that the accident was not wholly divorced from lack of forethought or breach of common-sense precautions, even if the charge of culpable negligence were not admissible."

That mental attitude should always be maintained. Continuous alertness towards even the remotest chance of disaster is the best safeguard against its occurrence.

The other constant problem is the maintenance of an adequate supply. The term "adequate" cries out for definition. Is it to be measured by the standards of great cities so fortunately situated as to have water abundantly available, so that they have at command such quantities as to make waste of no account and economy a profitless virtue? Or is it to be measured by the actual necessities for health and cleanliness and comfort, including such services as the watering of gardens and the washing of motor cars, as well as for manufacturing and trade purposes? All this, of course, subject to regular inspection, and to persistent education of the public in the individual duty of avoiding the running to waste of what is an absolute necessity for the welfare of the community at large. If the former, then the London water supply is hopelessly inadequate; if the latter, a fair case can be stated for its minimal sufficiency. From present sources there is no possibility of obtaining the fifty or sixty gallons a head a day of which some great populations can boast; but London may be able to work away, at least until better times come. Sir Alexander Houstoun indicates that the Ministry of Health would regard the low figure of sixteen gallons a head a day as not inadequate for domestic purposes, and in London manufacturing requirements are not nearly so great as in the industrial areas. At the best the position cannot be regarded with entire equanimity, but it may be taken for granted that the experience of last year will result in the whole position of the supply being reviewed and every effort made to provide against the risks which attach to the vagaries of the rainfall. Last year it was only about 17 inches, a figure which has no parallel in the sixteen years for which the records are tabulated in Sir Alexander Houstoun's report.

The report deals in the usual careful and detailed fashion with all the activities of the water department. Chlorination continues to be a main factor in the protection of the consumer against pollution. Three main objections to it are a sentimental dislike of "doped" water, an occasional unpleasant taste, and the fact that its use may be regarded as a short cut to purity. But the author of the report holds that chlorination has a great future—that it saves pumping, supplements other measures which are apt to fail under adverse weather conditions, can probably make almost any

water epidemiologically safe, has led in a number of instances to the reuse of abandoned sources of supply, can be resorted to as a temporary measure in emergencies, can be applied for protection of water in difficulties which arise in the cleansing of low-lying filter beds, and, when combined with rapid filtration, gives a safer result than slow filtration without chlorination. The methods—gaseous, liquid, and solid—of administering chlorine to water are stated as constituting a brief reply to many queries which the author of the report has received.

The diminished prevalence of enteric fever has already been referred to, but the statistics which Dr. Hamer, medical officer of the London County Council, has furnished to Sir Alexander Houston are so striking that some of them may be noted here, though the area to which they refer is not contemporaneous with "Water-London." In 1900 the cases numbered 4,292, and the rate per 100,000 living was 95. By 1903 the cases had fallen to 2,339, and the rate to 51. During the next eight years, 1904 to 1911 inclusive, the cases gradually diminished from 1,896 to 1,022, and the rate from 41 to 23. Then the cases fell below 1,000 per annum, and have steadily gone down from 704 in 1912 to 329 in 1921, the corresponding rates being 16 and 7 per 100,000 inhabitants. It is not alleged that all this is due to the work of the Metropolitan Water Board, for a great reduction in enteric fever has taken place throughout the whole country. The point is made to indicate how much less risk there now is of contamination of a water supply by that infection than there was at the beginning of the century.

LYING-IN HOMES.

A by-law has been added by the London County Council under its General Powers Act, 1921, to the regulations governing lying-in homes. The new by-law, which does not take effect until it has been confirmed by the Minister of Health, prescribes the records which are to be kept with regard to the persons received and the business carried on at a lying-in home, and requires the notification to the Council of any death occurring at such a home. The keeper of a lying-in home will be required in future to keep a register of patients received and to state the date and hour of the delivery of the patient, the name of the doctor or other person in attendance, and the date of the patient's discharge. The register must also contain particulars of the death of a patient or of any infectious disease from which she was suffering while in the home.

ATTENDANCE ON FIREMEN AND DRAIN WORKERS IN LONDON.

The London County Council provides free medical attendance for its firemen and the men employed on the main drainage (altogether about 2,170 persons). The county is divided into twenty-five districts, and a medical officer is appointed for each. Before the war the district medical officers were paid at the rate of 10s. a year for each man entitled to medical attendance. This rate has been increased since December, 1918, to 11s. 6d. a year. The fee includes the provision of all requisite medicines and simple surgical appliances, as well as ordinary certification. It is reckoned that the Council's fees approximate to the capitation fee for insured persons (9s. 6d., exclusive of medicines and dressings), while they are considerably less than the fees paid by the Metropolitan Water Board (15s. a year for each person). It was resolved at the last meeting of the Council to continue the present fees until December 31st, 1923, when they will be reconsidered.

Scotland.

SIR JAMES HODSDON AND EDINBURGH ROYAL INFIRMARY.

At a meeting of the Board of Management of Edinburgh Royal Infirmary on August 7th a minute was adopted in regard to the retirement of Sir James W. B. Hodsdon, senior surgeon of the infirmary, from its active staff. The Board placed on record its deep appreciation of the great services which he had rendered to the institution, not only by his dexterity as a surgeon, but by the sagacity and sound judgement with which he had exercised his skill, by his broad sympathy with the suffering, and his courtesy to his fellow-workers. He was invited to become an honorary consulting surgeon to the infirmary.

THE VITAL STATISTICS OF SCOTLAND FOR 1920.

The Scottish Registrar-General's Report for 1920, referred to in our issue of July 29th (p. 176), has now been issued. Its completion was delayed until the results of the 1921 census of Scotland were available for use in the compilation of statistics. The year was one of maxima and minima. The births and marriages were the highest ever recorded; the death rate and the infantile mortality rate were the lowest. This must surely be a unique as well as a most satisfactory grouping of statistical facts relating to one and the same period of time. But the Registrar-General evidently regards it as outside his province to indulge in any kind of jubilation; he ploughs steadily on, looking neither to the right hand nor the left, through what a bad punster would call his figurative volume. We, however, take the liberty of congratulating all concerned, especially the Registrar-General and the Scottish Board of Health, on their *annus mirabilis* of 1920, and in a later issue we shall endeavour to garner some of the fruits of their labours. It is told of a famous health officer in the northern kingdom that on one occasion, meditatively marching along with his sanitary inspector to visit the scene of a nuisance, he suddenly broke the silence as follows: "Macpherson, have you noticed that the death rate in our town has been remarkably low this last month?" "Yes, Sir, I have noticed that." Then another half-minute of silence, ending again with: "Macpherson." "Yes, Sir." "Nao thanks to either you or me." It is the utter and obvious irrelevance of this story to the present occasion that gives us the safe opportunity of telling it.

THE CENSUS OF THE FOUR GREAT TOWNS OF SCOTLAND.

A preliminary report on the Scottish census of 1921 was published before the end of that year. Additional reports are now in course of issue, and include those of the four great towns of Scotland—Glasgow, Edinburgh, Dundee, and Aberdeen. It is a very notable fact that, apart from extension of boundaries, three of the four show a decrease in population, the only increase being in Glasgow. Unfortunately, however, the data are vitiated by the date on which the census was taken. Until 1921, April was the census month, but in that year a labour strike made it necessary to defer the numbering of the people until June 19th, when many folk are already on holiday at the coast or in the country, though of course the rush does not occur until later—July and August in Glasgow, and August and September in Edinburgh.

Glasgow.

The population in 1911 was 784,496; but in 1912 extension of boundaries added areas of which the population at the census of 1911 was 223,991, making a total of 1,008,487 at that time. In 1921 the total was 1,034,174, being an increase of 25,687. This is a growth of only 2.5 per cent., but it is estimated that a census at the proper time would have shown at least 30,000 more. In 1801 the population of Glasgow proper was only 46,779, but the suburbs of Barony and Gorbals, long since included, made with the city a total of 77,385. At that time Edinburgh's population was 67,288, so that the two cities were much on a par. Now, even with Leith added, Edinburgh is not much more than two-fifths the size of Glasgow. Including extensions Glasgow is about fourteen times as large as in 1801. Its extended area is 18,589 acres; so that the population per acre is 55.63 persons. But such statements of density are of comparatively little value, because the centre may have a density many times that of the outskirts, and an extension of boundaries makes only a statistical change in that respect. The slums are as before, and the outer fresh air is brought no nearer to them than when the annexed areas were regarded as being within the territory of neighbouring authorities. Glasgow includes the whole or part of no less than eight parishes, varying in population from 587,030 downwards. It rejoices in fifteen members of Parliament, in whose divisions the populations range from 48,376 to 92,856. For every 100 males in Glasgow there are 105 females, whilst in Edinburgh the ratio of females is 119, in Dundee 125.4, and in Aberdeen 118.6, per 100 males.

The effect of the war is seen in the age constitution of the population. Males from 40 upwards have increased, but from 20 to 40 they are fewer. The mean age of the population, including both sexes, was 28.7, against 27.1 in 1911. In females the mean age was slightly higher than in males. In Edinburgh the mean age was 31.2, in Dundee 30.5, and in Aberdeen 29.8. As to conjugal condition, at ages from 15 upwards, the unmarried women were only 2.4 per cent. more numerous than the unmarried men, whilst in Edinburgh the excess percentage of unmarried women was 35.

Housing.—In Glasgow 12.8 per cent. of the population are living in houses of one room, 49.8 per cent. in two-roomed

houses, 20 per cent. in three-roomed, 6.1 per cent. in four-roomed, 2.9 per cent. in five-roomed, and 1.6 per cent. in six-roomed.

The chief occupations are: Workers in metals, 101,540; in transport and communication, 54,598; in commercial occupations (excluding clerks), 53,954; clerks (not Civil Service nor local authority), 39,360; personal service, 35,967; textiles, 26,590; wood and furniture, 23,271; professions, 17,850, including 666 medical practitioners.

Edinburgh.

The census population was 420,264, against 320,318 in 1911. The addition of close on 100,000 is more than accounted for by extension of boundaries, the added areas having had a population of 103,728 in 1911, so that there is a real decrease of 3,782 in the extended city. The added area itself, however, made an increase from 103,728 to 108,426, so the diminution in Edinburgh's former area was all the greater. The Edinburgh of to-day has six times the population it included in 1801, and double what it had in 1881. The area of extended Edinburgh is 21,524 acres, or very nearly the double of what it was before the extension, and is nearly 3,000 acres more than that of extended Glasgow, so that its nominal density is only 12.97 persons per acre, but that aspect of the matter has already been mentioned in relation to Glasgow. There are in Edinburgh 36,238 more females than males, the ratio as already noted being 118.9 to 100. Of the female population over 15 years of age 45.41 per cent. were unmarried, 42.04 married, 12.40 widowed, and 0.15 divorced.

In one-roomed houses 4.7 per cent. of the population live, in two-roomed 32.9, in three-roomed 22.5, in four-roomed 13.9, in five-roomed 6.0, and in six-roomed 3.7 per cent. These figures are much better than Glasgow's. Amongst occupations the professions bulk largely in Edinburgh, the total being 15,199, male and female. They include 4,461 teachers, 2,048 sick nurses, 972 lawyers, 612 doctors, 579 ministers, clergy, monks, and nuns, 167 dentists, and 3,680 professional students.

Dundee.

The census population was 168,315, being a nominal increase of 3,311 over 1911, but in the interval extensions of boundaries took place, bringing in a population of 11,347, so that in the extended area there has been a diminution of 8,036, or 4.6 per cent. In 1801 the population was 26,084, or about one sixth of what it is now. The extended area of the city is 6,555 acres, and the nominal density 25.63 per acre. The excess of females over males is 18,957, the ratio being 125.4 females to 100 males. Over 15 years of age the excess of females is 36.9 per cent. In one-roomed houses there live 8.9 per cent. of the population, in two-roomed 50.8 per cent., in three-roomed 20.9, in four-roomed 7.0, in five-roomed 3.1, and in six-roomed 2.1. The chief occupations are textiles (flax, hemp, and jute workers) 35.8, per cent. of the total, metal workers 10 per cent., commercial occupations (not clerks) 8.7, transport and communication 7.2, and personal services 5.9. Of the textile workers three-fourths are females, and the total number of persons in this employment is 36,659.

Aberdeen.

The population numbered 153,963, being a decrease of 4,928, or 3.0 per cent. In 1801 the population was 26,992, and this is the first census which breaks the continuous growth since then. There is an excess of females over males of 13,523, or 118.6 to 100. The average age of the entire population is 29.8 as against 27.6 in 1911. In one-roomed houses there live 4.4 per cent. of the population, in two-roomed 32.6 per cent., in three-roomed 31.5, in four-roomed 12.5, in five-roomed 3.5, and in six-roomed 3.7. The figures are better than those of 1911. The principal occupations, stated as a percentage of the total occupied persons, are: transport and communication, 12.8; commercial occupations (excluding clerks), 11.6; personal service, 9.3; metals, 8.4; clerks (not Civil Service nor local authority), 6.6; professional occupations, 5.8; wood and furniture, 5.5; and textiles, 5 per cent. Workers in stone are 4.3 per cent., and fishermen 2.8 per cent. Of the transport workers 1,264 are connected with railways, 2,826 with roads, and 2,956 with water transport.

Housing.

The following table shows for each of the four cities the percentages of population living in houses of from one to six rooms stated separately.

No. of Rooms.	One.	Two.	Three.	Four.	Five.	Six.
Glasgow	12.8	49.8	20.0	6.1	1.6	1.6
Edinburgh	4.7	32.9	22.5	13.9	6.0	3.7
Dundee	8.9	50.8	20.9	7.0	3.1	2.1
Aberdeen	4.4	32.6	31.5	12.5	3.5	3.7

In this respect it will be observed that Glasgow and Dundee are in decidedly a worse position than Edinburgh and Aberdeen, but according to English standards none are good. Speaking broadly, the same system of housing exists in all the four cities—great buildings (curiously called "lands") three or four stories high, each with multiple dwellings on every floor, opening off a common stairway. Much improvement in detail is to be found in the more modern houses, but the system in its essentials remains. It goes far back into the past. Curiously, the terms "house" and "tenement" are in common speech used in opposite senses in Scotland and England. In England the actual dwelling is the tenement, whilst (if it does not stand apart as a cottage) the building of which it is a part is the house. But in Scotland the dwelling is the house, and the great building on one of whose floors it is situated is the tenement, or "land." If one of these blocks is for sale it may be described as "a land of houses," though the description is falling out of use.

Ireland.

IRISH ARMY MEDICAL COUNCIL.

Dr. M. R. J. HAYES, F.R.C.S.I., Lieut.-Colonel B. Forde (retired, R.A.M.C.), and Dr. P. J. Smyth, Fitzwilliam Street, Dublin, have been appointed whole-time officers of the new Irish Army Medical Council. The main duties of the Council will be to formulate a scheme for the organization of a medical corps for the Irish Free State Army.

APPOINTMENT OF A MEDICAL OFFICER.

The co. Arann Health Committee, when a vacancy occurred recently in the Dowra Dispensary District, advertised the post at a salary reduced by almost 50 per cent. Several abortive attempts were made to fill the post. The Irish Medical Secretary made representations to some intending candidates—mainly women doctors—who withdrew their applications when the position of affairs was explained to them. The Health Committee, however, in spite of the efforts of the medical organizations, succeeded in filling the appointment, and elected Miss O'Reilly, L.R.C.S.I., Dublin. The facts of the case were put before Miss O'Reilly, and she was informed of the withdrawal of the other candidates.

COUNTY WEXFORD MEDICAL PRACTITIONERS.

The following resolutions were passed unanimously at a recent meeting of medical practitioners held at Ennisceorthy:

1. That we are of opinion the notification of tuberculosis by the medical attendant should be with the consent of the patient unless the position of the patient is such as to be a danger to the community.
2. That the fees proposed to be paid to the profession for the notification of tuberculosis are altogether unacceptable for professional work, and inadequate when the importance of the duties is considered.
3. That in the circumstances we are of opinion that the profession in Ireland should await the directions of the Irish Medical Committee with regard to the scheme proposed by the Local Government Department for the notification of tuberculosis.
4. That we avail ourselves of this meeting to state that we have learned with much disappointment the decision of the Local Government Department that the County Health Board, the local profession on these boards. That we consider this decision as reactionary, and contrary to the precedent of medical representation, without any official disability, as provided under the Insurance Acts in the case of County Insurance Committees, and also contrary to the recommendation of the Irish Public Health Council that officials should be eligible to act as representatives of the profession on the local health bodies.

When the resolutions came before a meeting of the co. Wexford Health Board it was decided to send the resolution of the medical practitioners dealing with the notification of tuberculosis to the Dail for its observations.

THE New York City Health Department, on June 26th, opened a riverside convalescent camp on North Brother Island for patients suffering from whooping-cough, a disease with which about 500 children in the city were reported to be affected. Few of the hospitals have facilities for treating them during convalescence, but in the new camp there is accommodation for 2,000 children, who will be kept there for six weeks or longer without expense to their parents.

Correspondence.

STERILIZATION OF MENTAL DEFECTIVES.

SIR,—Dr. J. R. Whitwell writes (BRITISH MEDICAL JOURNAL, July 8th, p. 64): "The person who advocates sterilization assumes, first, that we know exactly how heredity acts, and secondly that by sterilization we should only prevent the production of the unfit." Doubtless none of us "know exactly how heredity acts," but surely all medical men know sufficient for the purpose. May I set down a few commonplaces of knowledge?

The individual is derived from a germ cell. Therefore he can inherit only through it. In the germ are none of the characters (for example, head, scar knowledge of Latin) which he subsequently develops, but only powers (potentialities, capacities) for developing them. Therefore he inherits not characters, but only potentialities. Characters arise in response to nurture—for example, food, moisture, light, heat, use, injury, internal secretions. The sum up of the individual's powers for development is his *nature*. The sum up of the influences which play on him and cause development or change is his *nurture*. The nature of the individual is rigidly fixed and limited and, therefore, he can develop only within the limits imposed by it. Thus the germ of a man can develop only into a man. But his nurture may vary within wide limits, and, therefore, he need not, and commonly does not, develop all that his nature permits. For example, he must develop a head, for without it he could not exist, but lacking the right injury, or teaching, he may not reproduce a particular scar or item of knowledge. Obviously, then, inheritance is one thing, and reproduction quite another thing. There may be inheritance without reproduction, but there cannot be reproduction without inheritance. Thus a germ which has inherited everything may perish before it has developed anything.

Offspring invariably differ from their parents somewhat. These differences are natural or nurtural, or a combination of both. Thus a man may be darker than his parent by nature, or by nurture, or by both. Technically, natural differences are termed "variations" and nurtural differences "modifications." It is agreed on all hands that variations are transmissible. The statement that modifications are transmissible is neither true nor untrue. It is merely nonsensical (see *Nature*, November, 1920, to May, 1922). It involves a play on words. The germs of some living beings (for example, plants, insects, fish, and reptiles) are cast naked into the world, exposed to all its vicissitudes; the germs of other types (for example, mammals) are sheltered within the body of the parent till development is far advanced, yet individuals developed from the former display, as far as is known, no greater range of variations than those developed from the latter. Thus, in a litter of puppies may be found as great a range of variations as in fish hatched from naked ova. The fact that some species that void naked ova have existed almost unchanged from geological time indicates how obstinate is the resistance of germs to enforced change of nature. Of course, every germ is liable to injury or other enforced change; but, like other living beings, it tends, if it survive, to recover and return to the normal. If it does not recover it tends to perish and leave no descendants. It follows that nearly all variations are "spontaneous"—that is, not caused by the action of nurture. They are experiments made by blind nature, groping towards improvement.

We are now in a position to formulate a law, which I think no one will dispute, and which covers the whole range of heredity. "Offspring vary spontaneously from parents; variation is the sole cause of non-inheritance; apart from variations, like exactly begets like if parent and child develop under like conditions."

But this law does not cover reproduction. For example, if white and negro mate, the offspring is mulatto. Mulattos, interbred, have mulatto offspring. With every infusion of white the touch of the tar brush grows fainter. There is blending in nearly all particulars. The most conspicuous exceptions are in sex and in eye colour. The child is a boy or a girl—hardly ever, if ever, hermaphrodite; and the eyes are black. But there is massive evidence derived from many species of animals that male is undeveloped female, and vice versa. Some sort of nurture, occurring early in life, turns the scale and makes the individual male or female. In rhiphides heat is the factor; for during summer only females are present which produce parthenogenetically; but, with

autumn chill, males appear. In hothouses only females occur for any number of years. It follows that the females inherit, but do not reproduce, the male characters. There is not alternate inheritance, but alternate reproduction—alternate patency and latency. As regards eye colour, when white and negro mate, black is prepotent; but the prepotency is weakened with each infusion of white; so that at length blue eyes suddenly appear. If there were alternate inheritance, not merely reproduction, the prepotency could not be weakened, and black eyes would occur in all descendants.

Of course, the patent sexual characters of the male do not tend to blend with the patent characters of the female. They belong to different sets. The patent characters of the male blend with the latent male characters of the female; and vice versa. There is, thus, universal blending. Now there is massive evidence that, when mating individuals differ sharply in a particular other than sex, the reproduction in that particular often follows the sexual pattern. Sometimes the latency of such a character is prolonged. Man, as Darwin noted, has often seized on such sharp differences to create his cultivated plants and domesticated animals and, therefore, in them long latent ancestral traits tend to appear. Thus plants reproduced from seed often revert to the wild type. Pure-bred poultry and pigeons sometimes reproduce the ancestral coloration of *Gallus bankiva* and *Columba livia*, and if a horse be crossed with the broad-striped Burchell zebra the narrow stripes of the enormously remote Somali zebra are seen. Crossing is one of the conditions which cause latent ancestral traits to reappear. Hence the frequent re-appearance of them when fancy varieties of plants and animals, which are largely founded on abnormalities, are crossed. They never appear when wild types are crossed. It would seem that the horse has descended from the Somali zebra.

As all medical men know, the reproduction, not inheritance, of many human abnormalities (for example, club-feet, hare-lip, idiocy) is alternate. The abnormality may be latent for many generations, but at last conditions, probably analogous to those which govern eye colour, may occur which render it patent. Idiocy and its lesser degrees, imbecility, feeble-mindedness, and natural stupidity are particularly interesting. Man is the educable animal. The normal man can learn and has learned. The newly born normal infant can learn, but has not learned. The idiot cannot learn, and has not learned. There is a nutshell the difference between the extremest of human mental types. The perfect idiot cannot learn even to walk or speak. He differs from the normal man merely in this matter of learning; but the difference is enormous. He has lost the distinctively human character. Great abnormalities, occurring spontaneously, are rare. But idiocy is common, and becomes more so every year. It is impossible to account for its frequency except under the supposition—confirmed by the high proportion of idiots in tainted families—that idiocy is rarely a spontaneous variation, but is commonly the patency of an often latent trait. It does not matter in the least that bishops and ambassadors occur in families tainted with idiocy. Idiocy may be latent even in these exalted personages. Moreover, dignity of that sort does not usually imply genius, but, as a rule, only a golden spoon.

I do not know if Dr. Whitwell can find any error of fact or reasoning in the above. I have dealt only with matters within common experience. If I am correct, a single idiot may taint a whole race, and in that case doubtless we in England are extensively tainted. But it is possible by careful breeding to render an abnormality almost permanently latent—as in the case of the wild coloration of poultry and pigeons. I can imagine no way of effecting this in the case of mental defect except through sterilization.—I am, etc.,

Southsea, Aug. 15th.

G. ARCHDALL REID.

THE PREVENTION OF CEREBRAL HAEMORRHAGE.

SIR,—The death from cerebral haemorrhage of a public man aged 50 at a time of political crisis suggests the inquiry whether we are doing all that is possible to avert or at least postpone such disasters. It seems that brain workers everywhere, including prominent figures in the medical profession, are becoming more subject to these melancholy accidents, at the height of their powers and influence. Every year we see not a few men of the greatest experience and distinction lost thus prematurely to the country. Is it always inevitable? I think not.

There are not always obvious signs that a man is "on the verge of a stroke." He may indeed seem and feel exceptionally well, although not usually. It has fallen to me to

examine a large number of middle aged men. They were not ill, but they came, as all men in middle life ought to do periodically, to be "overhauled." Many observers besides myself have no doubt been warned in such cases by a spasmodic and irritable condition of the arteries. The state of contraction sometimes called "hypertonus" is clearly at first entirely spasmodic, for it may be readily relaxed under treatment (for example, venesection), or on the other hand increased by nervous and other disturbances. The arterial blood pressure naturally follows every wave of vascular contraction and relaxation. If the tension continues to mount there must come a time when, following perhaps on some mental or physical exertion or even a change of posture, an unsupported blood vessel gives way somewhere, if not happily on one of the mucous membranes then perhaps in the more delicate tissues of the brain.

In a paper read this year at a congress of physicians at Washington I suggested the systematic use of *blood-pressure charts*. Upon these charts the readings of systolic and diastolic pressures should be entered from year to year, or more often, and the resulting curve plotted out, so as to ascertain in cases under periodical observation whether the vascular mechanism showed signs of strain beyond the limits of safety. I pointed out that in many cases followed for a series of years a venesection at the right moment had produced an arterial relaxation out of all proportion to the amount of blood removed, and that the early symptoms of vascular breakdown had been entirely and promptly removed. The observations on which these conclusions are founded may, I hope, be published later. My object in this letter is to encourage the resort to venesection in cases of high tension as a preventive of cerebral haemorrhage. Some patients so affected ought to be bled once or twice in every year. For others a fairly free venesection at longer intervals seems sufficient. To find any ill effects from such a practice one must go back to the absurd excesses of former times. Its good effects are sometimes almost startling both to the patient and the medical man.—I am, etc.,

London, W., Aug. 15th.

R. FORTESCUE FOX.

THE TEACHING OF PSYCHOTHERAPY.

SIR,—Dr. McBride's letter in your issue of August 12th (p. 282) is most interesting, since it proves the very point he questions—the existence of the unconscious.

The reduction of dreams to the sexual is unacceptable to him, and he therefore seeks to prove that Freud contradicts himself by unconsciously quoting a sentence without its context. If he will reread the whole of the paragraph on page 454 of Freud's *Interpretation of Dreams* he will find that Freud is referring to a dream becoming a perception as the result of the sensory stimulus having directed part of the energy of the force-contents in the form of attention on the stimulant. It is to this that Freud refers when he says on page 197: "The dream is the guardian of sleep, not the disturber of it. We shall justify the conception with respect to the psychic factor of awakening elsewhere. . . ." Dr. McBride makes the mistake of regarding the mind as an anatomical entity, whereas it is the psychic link between perception and action.

The sexual theory of dreams is not by any means accepted universally. Even Freud says, "the majority of dreams of adults treat of sexual material and give expression to erotic wishes." Jung, one of Freud's foremost pupils, disagrees with the whole-hearted sexual theory and standardization of symbols. On the other hand, nobody denies that some dreams are of sexual origin and in any case a whole dream or part of it may be overdetermined.

No analyst suggests a sexual or any other interpretation to his patient—the interpretation must be that of the dreamer or the value of free association would be lost. The analyst's part consists almost entirely in keeping his patient from wandering too far from the subject and urging him on when resistances present themselves. It is in the latter connexion that auto-analysis usually fails, which is to be expected from the nature of conflicts.—I am, etc.,

JAMES W. W. ADAMSON.

Canstock Chase, Aug. 12th.

SIR,—Dr. McBride accuses Professor Freud of making contradictory statements. The latter is stated to have said on page 454 of his *Interpretation of Dreams*: "We must, therefore, admit that the dream invariably awakens us," and

again, in the *Introduction to Psycho-analysis*: "We do not wake up out of all dreams."

May I suggest that it is not fair to any writer to drag such remarks from their contexts? The former quotation occurs in the exposition of a wonderful attempt to formulate a theory of the mind which calls aloud for consideration as a whole. The meaning implied is that the perception in consciousness of the dream is equivalent to the awakening of the fore-conscious; it does not necessarily involve the termination of sleep. One of Freud's definite view-points is that dreams are the protectors of sleep.

Again, with regard to symbolism, symbols are not "the elaborate code of the psycho-analysts"; they are the conscious and unconscious property of us all. I believe a recognition of the unconscious is admitted by psychologists of most schools of thought.

Is it permissible to add that Freud cannot be understood from "desultory reading" by "one who is neither a neurologist nor a psycho-analyst"?—I am, etc.,

W. S. WILLMORE,

Bournemouth, Aug. 13th.

Lieutenant-Colonel I.M.S.

ARSENIC IN ULCERATIVE ENDOCARDITIS.

SIR,—Having retired from practice since April, 1918, after many years of active work, I feel some diffidence whether to write this letter upon the subject of ulcerative or malignant endocarditis, in the hope that the great fatality attending this affection may be minimized. I can only recall some three or four cases in my practice, and therefore conclude that, fortunately, the disease is not common; nevertheless, considering the great mortality, it was my intention to try the influence of arsenic as a sort of forlorn hope in overcoming the causes of this mortality, which undoubtedly to a great extent is due to the septic poisoning resulting from an open raw surface in a vital channel containing the necessary purifying blood for the life of the body. The question naturally arises, How is this poisonous secretion to be purified and the healing of an open wound thus promoted? Most of our antiseptic remedies cannot be tried in sufficient strength to be of any use. Arsenic, however, from its great power, judiciously administered, is worthy, in my opinion, of a trial, though we will be sailing between Scylla and Charybdis. The preparation used should be the sodium salt, which is preferable to any other; the earlier this fatal affection is treated thus the better the prospect of success, and it should be given in a liquid form and in as large doses as the patient can safely tolerate; as soon as evident improvement is manifested the dose should be gradually diminished, never giving more than what may be absolutely necessary.

This is an open letter to the profession for due consideration as a possible means of mitigating the influence which a foul wound would have upon the system. Hitherto I have not seen any statement of this remedy having been tried, hence the reason of my suggesting a trial being made by the profession.—I am, etc.,

Leamington Spa, Aug. 15th.

JOHN LYCETT, M.D.

THE GROWING ABUSE OF COCAINE.

SIR,—An article in the *BRITISH MEDICAL JOURNAL* of August 19th draws attention to a subject of importance to those of us who have occasion to prescribe cocaine for legitimate purposes. The present law hedges its prescription by irritating documentary formalities. Cannot the abuse be attacked at its source?

For many years substitutes for cocaine—such as alypin, stovaine, eucaine, novocain, and others—have been suggested. Each has claims, each objections, and none approaches cocaine in general efficiency.

In a recent number of the *British Journal of Ophthalmology*¹ I called attention to a new synthetic preparation, butyn, which, as far as ophthalmic surgery is concerned, seems to me, after six months' experience of it, to be a perfect substitute for cocaine. During that period I have had no occasion to go beyond it in any case requiring local anaesthesia. In the United States a committee of well-known ophthalmic surgeons appointed by the American Medical Association has reported on butyn in a most enthusiastic way, pointing out that for practically all purposes it is superior to cocaine.

Is not the time also ripe in this country for an authoritative investigation of its claims? I would suggest that a committee appointed by the British Medical Association or by

the Royal Society of Medicine should consider the whole question of local anaesthesia, with especial reference to substitutes for cocaine.—I am, etc.,

Lath, Aug. 20th.

W. M. BEAUMONT.

WOOD-HILL FUND.

SIR,—This fund being now closed with the publication of the tenth and last list of subscriptions, it would seem desirable to make some comments on the importance to the profession of the verdict given in this case, and to give some details about the fund itself.

An action was brought against Dr. Wood-Hill of Beccles for alleged negligence in the treatment of a lady who was suffering from a fractured femur, the result of an accident. The case was reported in your issue of November 26th, 1921. Notwithstanding that evidence was brought forward to show that Dr. Wood-Hill treated the case by approved modern methods, and that when the lady left his neighbourhood to go to her own home he urged her to consult her own doctor, and to be guided by his advice before she put any weight on the limb, the jury returned a verdict for the plaintiff with damages to the amount of £750.

The verdict at once excited widespread sympathy with Dr. Wood-Hill, as it was felt that a serious miscarriage of justice had taken place. Unfortunately, Dr. Wood-Hill had neglected to join one of the medical defence societies, and for this lack of foresight no exsconso can be offered. The costs of the action with the damages awarded came to the large sum of £2,250. The fund to assist him in this serious emergency was started by a letter of appeal signed by us in your issue of December 3rd, 1921.

The verdict is of great importance to the medical profession. It proves that although a medical man may have exercised all the skill at his disposal, and adopted approved modern methods in the treatment of a case, yet he still has to run the risk of an adverse verdict if the case does not finally do well. We feel this to be an unjust widening of a medical man's responsibility in the practice of his profession. Prior to the case of Clayden v. Wood-Hill a medical practitioner might feel fairly confident that if in the treatment of a case he used the ordinary care and skill which could rightly be expected of him he ran small risk of an adverse verdict in an action for alleged negligence. This is no longer so.

The moral to be drawn is that in no circumstances should a medical man engage in practice without being a member of one of the medical defence societies. Further, no medical man, after the warning which the profession has received by the case of Clayden v. Wood-Hill, need expect in any future similar case to be treated by his fellow practitioners with the generosity accorded to Dr. Wood-Hill.

A few details about the fund may be of interest to your readers:

Total amount subscribed	£	s.	d.
Bank interest	1,717	4	4
	19	13	10
	1,736	18	2
Expenses	6	5	0
Net total	1,730	13	2

A cheque for this amount has been forwarded to Dr. Wood-Hill.

The fund was made up of the following amounts:

33 Divisions of the British Medical Association subscribed...	£	s.	d.
4 Branches of the British Medical Association subscribed...	66	14	10
14 Medical societies subscribed	150	17	0
14 Honorary medical staffs of hospitals subscribed...	132	7	0
4 Local Medical and Panel Committees subscribed	56	19	6

Subscriptions from individuals were responsible for the remainder of the fund. The highest individual subscription was 25 guineas; the lowest 2s.

The widespread interest taken in this case is shown by the fact that subscriptions were received from such far distant places as New Zealand, Tasmania, Queensland, Toronto, Oporto, Nigeria, Khartoum, South Africa, and Baghdad.—We are, etc.,

ROBERT JONES (Liverpool).
GEORGE E. GASK (London).
R. C. ELSLIE (London).
JOHN LYNN-THOMAS (Cardiff).

Dr. D. Kennedy, Newbury.

The Services.

STATISTICAL REPORT OF THE HEALTH OF THE NAVY FOR 1915.

THIS report was only published in 1922, the delay being due to the pressure of work on the Medical Department during the war and to the great accumulation of material since. It is, however, greatly to be deplored that the figures should not have been available before. The report covers a very interesting period of the war, when large numbers of ships were employed and the casualties from injury and disease from the Gallipoli peninsula were very heavy, though, as stated on page 153, the returns of the Expeditionary Force of the Royal Naval Division are not included.

The average strength of the total force was 236,500, the total number of cases of disease and injury was 146,805, giving a ratio of 620.73 per 1,000, a decrease of 5.72 in comparison with the average of the previous five years. The average number of men sick daily was 5,289, or 22.1 per 1,000, being 2.1 less than that of the previous five years; each person is computed to have lost 8.16 days' service for the year. The total number finally invalided from the service was 5,689, the invaliding ratio showing an increase of 9.26 in comparison with the average of the previous five years; but it is

pointed out that this is largely due to the fact that many of the R.N.R., R.F.R., and R.N.V.R. who had been called up in the war were found to be physically unfit. The total number of deaths was 216, giving a ratio of 22.05 per 1,000, which was considerably less than that of 1914; of these, 825 were due to disease, and 4,391 resulted from injury, including those killed and wounded in action; in the latter category were 834 wounds and fractures, 2,536 wounds in action, 23 burns and scalds, 922 drowned, and 33 suicides; 39 were from the *Formidable*, 511 from the *Goliath*, 196 from the *Argo*, 127 from the *India*, 56 from the *Triumph*, 42 from the *Majestic*, 66 from the *Lygon*, and many smaller numbers from isolated ships, trawlers, etc. A full and interesting list of these casualties is given, stating the geographical position of the ship, and whether the casualties were due to torpedo, mine, or other cause.

The zymotic diseases were practically all contracted on the home station and in the Grand Fleet. Influenza is recorded in 6,235 cases, with only 4 deaths; this is a great increase of cases over that of the previous five years' average: there were also 14,400 cases of catarrh. Diphtheria caused 85 cases with 4 deaths, and cerebro-spinal fever 115 with 67 deaths—a very high mortality, probably due in part to the overcrowding of the Royal Naval Barracks at Portsmouth, Chatham, and Plymouth, which returned respectively 24, 20, and 13 cases. There were 446 cases of enteric fever, of which 62 were diagnosed as paratyphoid A and 1 as paratyphoid B, but it was often impossible to determine properly the differential diagnosis. The *Febrile* returned 32 cases among men drawn from the beach parties on the Gallipoli peninsula, the *Blenheim* 20 cases, mostly from men of the R.N.R. and R.F.R. from tenders; here were not inoculated, whereas from the ship's company there were only 2 cases. Mediterranean or undulant fever gave 27 cases, a great increase over the average of the previous five years—namely, 0.11 per 1,000 as compared with 0.03. Dysentery yielded 351 cases, of which 725 came from the Mediterranean; the majority are said to have been amoebic, and the results of emetine treatment were satisfactory. Malaria produced 1,607 cases, but only two deaths are recorded; most of the cases were of African origin, contracted on the west coast. The tuberculosis return shows a very slight decrease over the average; a specially interesting table gives the number of cases and ratio per 1,000 for the different ratings: for commissioned and warrant officers it was 1.5 to 1.5, for seamen, marines, and general hands it was 2.0 to 3.0, but for the sick berth staff it rose to 5.4 and for ship's stewards and cooks to 19.5; the reason for this requires explanation. The total number of cases of venereal disease was very high, but one reads with pleasure that there was a noticeable decrease in the case ratio per 1,000 for each *venereal disease*: the highest rate was on the China station and the lowest on the Cape station; the total number of days lost to the service was 223,947. A table showing the ratio of sickness per 1,000 in the different fleets is instructive: Home 28.6, Grand 18.3, Mediterranean 24.9, West Atlantic 16.5, China 41.5, East Indies 26.3, Cape of Good Hope 29.4, Irregular 30.4. The highest ratio was found on the China station and was largely due to venereal disease; the total force was averaged at 720 men, employed in a receiving ship, a depot, and two sloops.

The hospitals both at home and abroad were fully occupied, and many subsidiary hospitals had to be used. The eleven hospital ships treated in all 26,614 men, of which 15,747 were military; the *Vera*, *Sumali*, and *Soudan* were employed in the eastern Mediterranean and were worked to the fullest capacity both for surgical and medical cases.

Obituary.

ARTHUR MARMADUKE SHIELD, M.B., B.Ch. Camb., F.R.C.S.,
Consulting Surgeon to St. George's Hospital.

THE announcement of the death of Arthur Marmaduke Shield at the hotel in the Island of Colls, Hebrides, on August 5th, after a seizure on July 30th, recalls a striking personality and the disappointment of that full measure of success which was confidently anticipated for him when ill health necessitated his premature retirement in 1907. He was born in 1858 at Landawke, Longharne, Carmarthen, and was the son of William Henry Shield of Gilfach, Pembrokeshire. He was educated privately, and entered the medical school of St. George's Hospital in 1875; he had a most distinguished career as a student, winning the Brackenbury prize in surgery and the William Brown (£40) exhibition in 1878, and the William Brown (£100) exhibition in the following year, when he took the M.R.C.S. and L.R.C.P. and became house-surgeon. In 1881 an important event in his life occurred, for he obtained the appointment of house-surgeon at Addenbrooke's Hospital, Cambridge, and thus came under the influence of that great teacher, Sir George Humphry, whom he assisted in private and in many respects resembled. His three years at Cambridge left their impress on his character and gave him a university experience and degree, for he was contemporaneously, as was then possible, an undergraduate at Downing College. In 1883 he achieved the feat of passing the two parts of the F.R.C.S. in the same month, and in 1884 he returned as resident obstetric assistant to St. George's, where he was also anaesthetist and in 1886 curator of the museum, a recognized step

to the staff. In the same year, however, he was attracted away as assistant surgeon to the Westminster Hospital, but soon after migrated to Charing Cross Hospital, where for the next seven years he was assistant surgeon, aural surgeon, demonstrator of anatomy, and lecturer on practical surgery in the medical school. At this period of his career he was associated with the late Dr. Montagu Murray as a private coach, many men up for the surgical examinations passing through his hands, and was busily engaged in many other directions. In June, 1893, he was called back to St. George's as assistant surgeon, becoming later (1895) surgeon to the throat department, and in 1900 full surgeon. He held also the posts of surgeon to the Waterloo Road Hospital for Women and Children, and to the Hospital of St. John and Elizabeth, and was secretary of the Medical Society of London, the old Dermatological Society, and of the Surgical Section of the British Medical Association at its annual meeting in London in 1895. He was also an additional examiner in surgery at his old university and an examiner at the Apothecaries' Society. In 1907 he had the terrible experience of inoculating himself during an operation, and his health was so gravely affected that he was obliged to give up work, at the age of 49, and to retire to the country. After a long illness, necessitating many operations, his health improved, and during the war he gave his services as consulting and operating surgeon to a military hospital at Exmouth, near Budleigh Salterton, where he had settled down.

Shield's literary output corresponded with his all-round activities and bore witness to his ability as a general surgeon with special knowledge in otolaryngology and dermatology. His efficiency in these special departments was shown by his books on *Diseases of the Ear* (1894), his *Lectures on Nasal Obstruction*, and the articles in the first edition of Allbutt's *System of Medicine* on diseases of the nails and tumours of the skin; his contribution on dislocations and joint injuries to Treves's *System of Surgery* and on diseases of the breast to Quain's *Dictionary of Medicine* prove that he was regarded as a prominent general surgeon. He also published a volume of *Surgical Lectures and Essays*, but his chief work, embodying observations and collection of cases over many years, was *A Clinical Treatise on Diseases of the Breast*, which appeared in 1898 and was a well-balanced, practical, and up-to-date account of this important and extensive subject.

His wide experience made Shield a popular and most successful teacher of students; he was above all things practical, and, besides insisting on the principles of surgery, laid stress on matter that would eventually prove of importance in private work. His method of instruction was arresting and impressive, like that of his old teacher Sir George Humphry, and his fund of humour and anecdote was often utilized to drive home his points and, indeed, rendered them difficult to forget.

A man of strong and independent character, he was no respecter of persons, certainly never sought favour by kneeling under to seniors, and had fearlessly fought his way up by his unaided efforts. In spite of some adverse conditions, among which must be reckoned threatened tuberculosis in early professional life, the struggle was successful, but he emerged in watchful and resourceful opponent in debate and often appeared somewhat cynical, and so hid his real kindness of heart. His brilliant conversation and power of mimicry rendered him welcome socially, and he had close friends; but these gifts made others, possibly with reason, look intensely to the weak points in their armour and wonder what comments they might excite. Apart from his profession he had many interests: he was devoted to fishing, played golf, and had an intense love of the country, to which he always intended to retire long before his full time at the hospital was run. As it was, an evil fate determined that this should occur prematurely, and his career, interesting from its high promise and achievements, rather sadly illustrates the changes and chances that may beset a consulting surgeon.

H. R.

WILLIAM THOMAS, F.R.C.S.,
Birmingham.

By the death of Mr. William Thomas of Birmingham the medical profession of that city loses one of its oldest and most esteemed members. He was the son of Dr. Robert Thomas, and was born near Leeds in 1840; he entered Queen's College, Birmingham, as a medical student in 1862, and had a very distinguished career. In 1865 he obtained

the diplomas of L.S.A. and M.R.C.S.Eng. He then held the post of resident medical officer to the Bradford Infirmary, where he remained for two years, and on returning to Birmingham he took the M.B.Lond. in 1867 and the F.R.C.S.Eng. in 1869.

He was professor of anatomy at Queen's College, Birmingham, from 1874 to 1884, being given the title of emeritus professor on his retirement from the chair. He was pathologist to the Queen's Hospital from 1874 to 1878, surgeon to the Children's Hospital from 1874 to 1894, and surgeon to the Orthopaedic and Spinal Hospital from 1883 to 1908; to both of the last-named institutions he remained a consulting surgeon up to the time of his death. In 1888 he was appointed Ingleby lecturer for the year. He was a past-president of the Midland Medical Society, and his contributions to medical literature were numerous and important. He is survived by his widow, three sons, and two daughters.

Dr. WILLIAM BLACK ALEXANDER died in a nursing home in Edinburgh on August 18th at the age of 78. He was educated at the Edinburgh Institution and University and took the diploma of L.R.F.P.S.Glasg. in 1869, and carried on a large practice in Edinburgh for forty years. He was also for many years a district medical officer under the Edinburgh Parish Council, and since 1911 surgeon apothecary to H.M. Household at Holyrood Palace. At one time Dr. Alexander was physician to the City Fever Hospital. He was elected a Fellow of the Edinburgh Obstetrical Society in 1882. His favourite recreation was golf, which in his earlier days he played with enthusiasm. Dr. Alexander's wife died some twelve years ago; one of his four sons is medical superintendent of the Aberdeen City District Asylum.

Universities and Colleges.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.
THE Goldsmid Entrance Exhibitions, 1922, of one hundred and twelve guineas each, have been awarded to Mr. P. M. D'Arcy Hart and Miss Janet Vaughan.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following candidates have been approved at the examinations indicated:

Primary Fellowship Examination.—R. F. J. Henry, Lucy M. Joly, A. J. Mooney, A. F. O'Carroll, R. W. Power, F. H. Whyte, W. K. C. Wynne.

Final Professional Examination.—C. D. Dykman, H. O. Mackey, S. A. McSwiney.

CONJOINT BOARD IN IRELAND.

THE following candidates have passed the examination indicated:

Final Fellowship Examination.—Henrietta C. Ball, J. T. Barrett, H. T. Begg, S. S. Brass, Mary F. J. Connolly, E. M. Dodd, P. Fleming, J. A. Flynn, P. J. Greene, V. E. Lee, M. Levy, J. J. A. Loftus, D. S. Magner, Gladys C. M. Marshall, J. S. Matthews, M. P. Moran, Maggie M. Nelson, J. F. O'Connell, The O'Rourke, F. E. Preston, W. E. Rutledge, W. Sherowitz, R. T. Taylor.

Medical News.

THE King has appointed Mr. John Herbert Gibbs, F.R.C.S. Edin., to be Honorary Surgeon-Dentist to His Majesty in Scotland.

THE Mayor of Weymouth, on August 17th, unveiled a bust of Dr. James Macpherson Lawrie, until recently senior physician to the Princess Christian Hospital, Weymouth, which has been presented to the hospital by a committee formed to commemorate Dr. Lawrie's great services to the hospital. It was originally founded by Dr. W. J. Smith for the treatment of diseases of women and children; through Dr. Lawrie's exertions it was rebuilt on a more appropriate site; a short time ago it was amalgamated with the other hospital in the town, the Royal Hospital. The bust was accepted on behalf of the hospital by Mr. Watts, chairman of the Hospital Committee. Dr. Du Boulay, at present senior surgeon to the hospital, expressed the pleasure of the medical staff and of the profession in Weymouth when they heard of the proposal, and the gratification with which they witnessed its realization. Dr. Lawrie, in acknowledging the compliment, said that he was glad to know that his bust would in future stand opposite that of Dr. Smith, the original founder of the hospital; a very exceptional man and one of his own best friends.

THE vacation course in general medicine, arranged by the Fellowship of Medicine, will begin on Monday, September 11th, and continue daily for two weeks until September 22nd. Copies of the syllabus and other information can be obtained on application to the Secretary to the Fellowship of Medicine at No. 1, Wimpole Street, London, W.1. A short comprehensive course on tropical diseases will be given at the School of Tropical Medicine, Endsleigh Gardens, N.W.1, during October. Copies of the preliminary syllabus are now ready and further details as to days and hours will be published shortly. Those desiring to attend the course should notify the Secretary to the Fellowship of Medicine as soon as possible.

AN Australian and New Zealand Medical Association in England has been founded to assist medical visitors to this country with information and, if it be desired, with advice. The Association is open to all medical graduates or undergraduates born in Australia or New Zealand and resident in or visiting England. The fee is one payment of 5s. Further information can be obtained from the honorary secretaries, Mr. E. T. C. Milligan, F.R.C.S., and Mr. Bedford Russell, F.R.C.S., 86, Harley Street, London, W.1.

COURSES of instruction in the diagnosis and treatment of fevers will be given at seven of the hospitals of the Metropolitan Asylums Board during October, November, and December. The fee for a two months' course is £3 3s., and for three months £4 4s. A three months' course of lectures and demonstrations on hospital administration will be given at the North-Western Hospital, Hampstead, by the medical superintendent, Dr. E. W. Goodall, on Mondays and Thursdays, at 5.15 p.m., commencing on Monday, October 2nd; the fee for the course is £3 3s. A two months' course of instruction in the diagnosis and treatment of fevers by the medical superintendent, Dr. F. M. Turner, will commence on Friday, November 3rd, at 11 a.m., and be continued on succeeding Tuesdays and Fridays; the fee is £3 3s. for the course. Further particulars can be obtained from the clerk of the Metropolitan Asylums Board, Embankment, E.C.4.

THE Ministry of Health has sent a circular to Poor Law authorities, transmitting a memorandum explaining the application of the Dangerous Drugs Act, 1921, to Poor Law institutions. The regulations made apply to the use of cocaine, heroin, opium, and their salts and preparations, but certain named preparations and prescriptions containing them are exempted. The medical officer of a Poor Law institution is required to sign all orders for these drugs, and to sign or initial all prescriptions containing them; he is further required to take all necessary precautions to ensure the safe delivery of the drugs, and is required to keep certain records concerning them.

A CIRCULAR has been issued by the medical department of the Board of Education with regard to the conditions under which minor dental work may be performed in connexion with the school medical service, by persons who are not registered dentists. The work must be performed under the personal supervision of a registered dentist, and must be limited to cleaning or polishing teeth, removing dressings or temporary fillings, and keeping records. The person concerned must be either a dental student who has received an approved degree of training (and who may be employed for not more than six months), a dental nurse of approved training, or a person already employed under arrangements previously approved. The registered dentist under whose personal supervision the work is performed must always be present when operative work is being done, must supervise a limited number of persons only, and must prescribe and be responsible for the treatment carried out.

THE Guild of St. Luke was founded in 1864, its object being the mutual encouragement and support of medical practitioners and medical students in leading a Christian life by communion, prayer, personal influence and example, and the promotion of works of mercy. It consists of students and practitioners of medicine, men and women, who are communicants of the Church of England or of any church in communion with it. The provost of the council of the guild is Mr. George Cowell, and a London hospitals' branch of the guild has been founded, with Mr. Raymond Johnson as master. The guild desires to appeal specially to medical students, by whom and for whom it was founded. The entrance fee is one shilling and the annual subscription not less than half a crown and not more than a guinea; further particulars may be had from the secretary, the Rev. H. Kirkland-Whittaker, M.D., Chaplain's House, Banstead Downs, Sutton, Surrey, or from the secretary of the Women's Ward, Dr. Isabel Pulteney, 2, Bryanston Place, W.1.

THE *Times* announces that the Quebec Government has decided to set apart 100,000 dollars (about £22,000) for the purpose of establishing a radium institute, under the control of the University of Montreal, for the experimental treatment of cancer.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

For postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL, SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY *Medicine*, Westrand, London; telephone, 2630, Ger. Office of the British Medical Association: Dublin Telegrams: the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

ANGER TO THE CHILD IN "TWILIGHT SLEEP."

DR. SYDNEY A. WINSTANLEY (Urmston, Lancs) writes in reply to Dr. H. D. O'Sullivan (August 12th, p. 283): "Out of a series of 239 cases in the last five years, I have not known any case in which 'twilight sleep' has endangered the child. There was only one stillborn child in the series. This was an impacted breech presentation, in which there was great difficulty in delivery. One child with congenital heart disease died after living twenty-four days. The remainder were all healthy children when I ceased to attend. Thirty-four cases were conducted in nursing homes, 6 in my own house, and the remaining 199 in the patients' own homes. Nearly half the cases were terminated by forceps, and in about half of these a general anaesthetic (CHCl₃) was given in order to keep the mother still. A few, perhaps fifteen, of the babies required some artificial respiration, but only one caused any real anxiety. This was an eight months premature baby; it eventually survived, and is now a healthy boy. In no case did the mother feel any pain or remember anything which occurred more than twenty minutes after the first injection. I would advise Dr. O'Sullivan to omit the use of morphine if he can expect the child to be born within 1½ hours of the first injection. It is in these cases that I have generally found the child needs some artificial respiration or stimulation before it cries lustily. In such cases a few drops of CHCl₃ given with each of the early pains will take the place of the morphine and will greatly aid the scopolamine in its action."

INCOME TAX.

"W.B." is a district medical officer to a parish council (part-time)—under condition that he resides and has a consulting room in his district. What allowances can he claim?

* * He can claim an allowance not only for a proportion of the rent—on any reasonable basis—but also for similar proportions of rates, lighting and heating, cleaning, and other general expenses.

"W. E. B." inquires whether he can legally claim an allowance for depreciation on an x-ray transformer.

* * No; that mode of allowance cannot legally be extended to the case of professional earnings. "W. E. B." however, should bear in mind that he can claim a deduction for the expense of maintaining the x-ray equipment by replacements from time to time.

"J. W. E. O." bought a practice which had deteriorated in his predecessor's hands. It had been assessed to tax at £300, but the current year's working should show a larger profit than that.

* * Our correspondent is entitled to assessment on the basis of the three previous years, but unfortunately has not complete evidence as to what those earnings were. We suggest that he get together what figures he can showing the probable gross receipts and expenses of his predecessor—the amount paid for the practice would be some evidence as to receipts—and see the local inspector with the statements. It seems to be a case where an amicable settlement should be possible.

"S. R. P." expects to be in the United Kingdom from May 15th to November 17th, 1922—that is, 185 days, but less than six calendar months. Will he be liable for British income tax?

* * In our opinion, No; unless he establishes a residence here.

"J. H." asks (1) whether the three years' average still applies to 1922-23, and (2) inquires as to the allowance due to him for a car renewal.

* * (1) Yes, except to the earnings of an "employment," which are now assessable on the amount of the salary, etc., for the current year; (2) apparently the car purchased is of a superior quality and the amount of the allowable expense is therefore the 1921 cost of the old car less £330, the amount allowed for it.

LETTERS, NOTES, ETC.

WE anatomists, said Méry, are like the porters of Paris, who know every street but nothing of what goes on inside the houses.

INFECTIVITY OF ARTIFICIAL DENTURES.

MR. F. TALBOT (Highgate, N.) writes: Mr. J. H. Badcock's advice (July 22nd, p. 150) as to the care of dentures is undoubtedly salutary, but it fails to make sufficient allowance for human frailty—perhaps one ought to say, for the deceptions of social life. Before the tribunal of hygiene the wearing of artificial dentures at night is quite indefensible; but it will infallibly be practised by people who are very sensitive about their appearance. Mr. Badcock denounces this motive as vanity, but it might sometimes fairly be called reluctance of feeling. I venture to suggest a practicable compromise. On retiring to bed replace the dentures, after they and the mouth have been thoroughly cleansed in the way Mr. Badcock suggests. Now, few people who are of an age to require artificial teeth sleep uninterruptedly throughout the night. At the first opportunity, then, let the dentures be removed and deposited in a metal box of platinum encrusted with jewels, of gold, silver, or aluminium, according to the means of the patient, which can be silently closed and secreted under the pillow. Or, still better, let them be placed in a little china toilet-box containing a mild antiseptic fluid and standing at the bedside. They can be removed at the first approach of dawn, the rosy-fingered. Then, in recommending that the gums should be thoroughly brushed, Mr. Badcock, I think, overlooks the fact that patients cannot be trusted to sterilize their toothbrushes, and are consequently liable to inoculate their gums with a prolific bacterial flora. I suggest the use of a rubber brush which can be kept permanently, except when in actual use, in antiseptic solution; or more simply, perhaps, the gums may be thoroughly massaged with the forefinger protected by a finger-stall, lubricated with a soft tooth-paste or dentifrice containing potassium chlorate. For the purposes of this discussion I am disregarding the undoubted danger contingent upon the wearing of small and insecure dentures during sleep.

CAESAREAN SECTION.

DR. C. M. CRAIG (Kendal) writes: The correspondence on Caesarean section in your recent issues makes melancholy reading, and I wonder—doubtless along with many others—why you allow such *hresido effusio* to be printed in the JOURNAL. I have never had the misfortune to read in the JOURNAL a more childish letter, and one in worse taste, than the letter which appears over the signature of James H. Martin, July 22nd date. Only a month past I assisted a colleague, a general practitioner, to perform Caesarean section in two urgent cases. He employed an incision through the rectal sheath, right side in one case, left side in the other. The uterus was likewise everted to facilitate removal of membranes, and the patients were nursed in the Fowler position. Let me add both did well. My colleague, so far as I can tell, does not suffer from the delusion that he was original in his methods, and I can guarantee that the fame of Dr. J. H. Martin had not reached him. I really think, Mr. Editor, you do owe us an apology for publishing such correspondence.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 25, 26, 27, 30, 31, and 32 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 28, 29, and 30.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 100.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

		£ s. d.
Line advertisement	per line	0 9 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be

1. Post Office to receive postal orders.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

138. Erythema Nodosum and Tuberculosis.

H. J. VETLESEN (*Tubercle*, July, 1922, p. 433) has scrutinized the records of more than 1,800 cases admitted to the Communal Hospital in Christiania in the 21-year period 1895-1915, during which he was medical superintendent. He followed two lines of research: (1) to collect the records of cases of erythema nodosum, to search for manifestations of tuberculosis in these patients or their relatives, and to ascertain the subsequent fate of the former; and (2) to collect the records of patients admitted with manifestations of tuberculosis, and to ascertain the frequency with which they had suffered from erythema nodosum. (1) There were 45 cases of erythema nodosum, as many as 42 being females. In 24 cases there was no family history of tuberculosis. Three cases were tuberculous at the time of the eruption, another three developed tuberculosis subsequently, and six were tuberculous suspects. Thus altogether 12, or 26.6 per cent., could be regarded as tuberculous. (2) Of 350 patients with pleurisy 18 had previously suffered from erythema nodosum, and of 1,317 patients suffering from other forms of tuberculosis 12 had previously suffered from erythema nodosum. Thus 5.1 per cent. of the patients with pleurisy, and 0.9 per cent. of the patients with other manifestations of tuberculosis, had suffered from erythema nodosum. In no fewer than 12 of the 18 cases of pleurisy the interval between the outbreak of this condition and of the erythema nodosum was only three and a half months or less. The author concludes that there can be little doubt as to the relationship of the two conditions, and he has learnt to regard erythema nodosum as a danger signal and as an incentive to vigilant supervision.

139. Decreasing Diabetic Mortality: Increasing Incidence of Glycosuria.

ELLIOTT P. JOSLIN (*Boston Med. and Surg. Journ.*, June 8th, 1922, p. 761) states that in the United States the highest recorded mortality from diabetes—that is, 17.5 per 100,000—was reached in 1915. In the subsequent quinquennium there has been a decrease, the lowest figure being 14.9 in 1919. From 1880, when the deaths recorded were 2.8 per 100,000, the rate rose steadily until 1915, no retrogression in the curve exceeding 0.2 per cent. "The decrease in diabetic mortality is by no means wholly attributable to a lessened frequency of the disease. It reflects better treatment." In the period 1898-1913 the average duration of life in fatal cases in Boston was 3.3 years. In 1915 the average was 4.3 years, and in 1920 it rose to 5.3 years. On the other hand, the records of the Metropolitan Life Insurance Company (*Statistical Bulletin*, November, 1921) show that whereas in 1919 sugar was found in 0.6 per cent. of specimens examined, the ratio in 1921 was almost doubled—that is, 1.1 per cent. Joslin cannot accept the theory that the increase in glycosuria is due to increased sugar consumption; he quotes statistics showing that in 1919 and 1921 the sugar consumption *per capita* was almost identical, although in 1921 the percentage of cases of glycosuria discovered was nearly double that of 1919. In his own practice, 300 successive case histories of "supposedly non-diabetics" showed sugar present in 50, a rate of 165 per 1,000. None of the patients suspected glycosuria, and only one case was "frank diabetes." Thus, while the Metropolitan Life Insurance Company's statistics showed 11 cases per 1,000, the writer's statistics for the same year yielded 165. This may be explained by the fact that the Insurance Company's cases were apparently healthy, while the writer's patients were ill.

140. Simultaneous Injection of Salvarsan and Mercury.

BOAS and PONTOPPIDAN (*Ugeskrift for Læger*, June 8th, 1922) warmly recommend the practice, introduced by Linsler, of giving salvarsan and mercury in one and the same intravenous injection. During the past six months they have treated 70 patients in all stages of syphilis, but not suffering from general paralysis or congenital syphilis, on this principle. The dosage was 0.2 gram neo-silver-salvarsan plus 1 c.c.m. novarsol or cysarsol at the first injection. The respective quantities of the salvarsan and mercury compounds at subsequent injections were 0.3 gram and 2 c.c.m., rising to 0.5 gram and remaining at 2 c.c.m. The intervals between the injections were half a week to one week, and after six intravenous injections the treatment was completed with four injections of 10 cg. ol. cinereum, so as to provide the patient

with a reliable amount of mercury. No ill effects from the combined administration of salvarsan and mercury were observed. After an observation period of only a few months it was too early to discuss the permanent results, but the immediate results were excellent from both the clinical and the serological points of view, and it was noteworthy that not a single case of neuro-recurrence was seen among these cases. The authors therefore regard this system as a definite improvement both from the patient's point of view and from that of his medical attendant, whose work is greatly simplified.

141. Recovery from Diabetes Insipidus.

TUCKER (*Amer. Journ. Med. Sciences*, May, 1922) records a case of immediate recovery from early diabetes insipidus after lumbar puncture, and instances three cases reported in the literature in which striking results followed the relief of intracranial pressure by the same means. A man, aged 27, with marked polyuria and thirst, complained of profuse sweating and of a dry feeling behind the bridge of the nose, which he associated with the cause of his thirst. Personal and family histories were negative, physical examination showed lungs, heart, blood pressure, reflexes, and glandular systems normal, and the sella turcica was normal on x-rays. Subjective symptoms pointed to involvement of the first, second, fifth, and eighth cranial nerves, and urinary analysis showed an output of 4,100 c.c.m. in fifteen hours, specific gravity 1005, no albumin, and no sugar. Following removal of 8 c.c.m. clear spinal fluid under normal pressure the profuse sweating ceased, and the urinary output dropped to 406 c.c.m. in twenty-four hours, and the specific gravity rose to, and remained at, 1026 to 1030, while the fluid intake became 1,200 c.c.m., as compared with 5,970 c.c.m. before lumbar puncture. Five and a half months later examination was negative except for evidence of hypopituitarism, as shown by a very high sugar tolerance. It would appear that the condition was the result of a serous meningitis with oedema of the infundibulum cerebri and involvement of certain left cranial nerves, pointing to the fact that anything causing obstruction to the flow of normal pituitary secretion, such as transient oedema, inflammatory exudate, or increased intracranial pressure, may, apart from destructive lesions of the gland, set up diabetes insipidus, and every case should be given the chance of early relief by lumbar puncture.

142. Chloroma.

CARONIA (*La Pediatria*, May 15th, 1922) reports the following interesting case of chloroma. A boy, aged 3, had measles and bronchopneumonia six months previously and recovered slowly; for the last two months he showed palpebral oedema and a progressive painful swelling in the left temporal region. He was pallid but not green; there was enlargement of the cervical glands. In addition to the tumour in the left temporal region, there were two smaller nodules in the parietal and occipital areas. There was slight ptosis and exophthalmos, and the optic disc was rather pale. The liver was normal, but the spleen was enlarged three fingerbreadths below the costal margin. There was some tenderness of the long bones. The red corpuscles numbered 3,030,000, white 6,100, and haemoglobin 55 per cent.; there was slight anisopoikilocytosis, a few normoblasts, and occasional megaloblasts and blood plates. Lymphocytes 17 per cent., monocytes 4 per cent., neutral polymorphs 59 per cent., acid polymorphs 1.4 per cent., mast cells, myeloblasts 0.9 per cent., myocytes 1.7 per cent., Türk cells 0.4 per cent., Rieder cells 0.6 per cent. The Wassermann reaction was positive in the mother, negative in the child. Examination of the bone medulla from the tibia and of the temporal tumour confirmed the diagnosis of haemocytohisto-myeloblastoma. A microphotograph of the sections is given. The absence of a typical greenish tint was explained by the scarcity of the typical green pigment in the growth. Etiologically the only factors noted were the positive Wassermann in the mother and the previous attack of measles. The author discusses the relation between leukaemia and chloroma.

143. Camphor in Nocturnal Enuresis.

C. POTOTZKY (*Deut. med. Woch.*, June 2nd, 1922, p. 730) warmly recommends the exhibition of camphor in nocturnal enuresis. He first gave it as camphora monohydrata, and the suggestion being made that its success depended on the bromine present he tried pure camphor alone, and found its effect equally beneficial. As bromine is apt to make the subjects of enuresis sleep even more deeply than usual, it is

wiser to give pure camphor or a camphor compound deprived of the unpleasant taste of pure camphor. The action of camphor on enuresis appears to depend partly on its sedative effect locally, and also on its ability to stimulate the cardiovascular system. A third factor may be its stimulating effect on the brain, the result being that the patient sleeps more lightly than usual. Though he recommends camphor, the author insists on adapting treatment to each of the many possible causes of enuresis, and he puts suggestion treatment and calcium medication in neuropathic children before camphor medication.

144. A Symptom in the Diagnosis of Early Phthisis.

IACONO (*Rif. Med.*, June 5th, 1922, p. 529), after corroborating the observations of Boerl respecting the tenderness along the edge of the trapezius muscle and the muscular atrophy of the same muscle in incipient cases of phthisis, describes a symptom he has observed himself. This is a tenderness on pressure over the first and second intercostal spaces, when the finger is placed in the axilla and pressed on this area. The author says he has frequently noticed this local tenderness, either in association with Boerl's signs or alone. The tenderness may perhaps be due to a little local pleurisy or may be reflex.

145. Injury to the Buccal Mucous Membrane by X Rays.

LAUE (*Zentralbl. f. inn. Med.*, April 22nd, 1922), who records two cases from the Bonn Skin Clinic, states that the first signs of damage to the buccal mucous membrane by x rays in the treatment of skin diseases of the face are redness and swelling of the mucosa and dryness of the mouth due to affection of the salivary glands. Difficulty in speaking and interference with mastication result. Treatment is purely symptomatic, and consists in washing out the mouth with bland lotions. Further, irritation by strong antiseptics should be avoided. Prophylaxis consists in reducing the deep action of the x rays to the minimum, especially in the treatment of skin lesions of the face.

SURGERY.

146. The Treatment of Tetanus.

DURING the interval between March 22nd, 1916, and December 7th, 1921, forty-nine patients with tetanus were admitted to the Los Angeles County Hospital. During this interval there were 74,393 total admissions, or one admission for tetanus to 1,518 admissions for all other causes. Twenty-six deaths occurred, or a mortality of 53 per cent. An analysis has been made by W. J. STONE (*Journ. Amer. Med. Assoc.*, June 24th, 1922) of the records of these forty-nine patients. The most important factor in the treatment of tetanus is its prevention. It should be the universal rule to give a prophylactic dose of 1,500 units of antitoxin to all patients who have received lacerated or penetrating wounds. If the wound contains necrotic tissue or a suspected foreign body the dose should be repeated in ten days, and subsequently if operation on the wound is contemplated. Treatment of all extensive lacerated wounds surgically by primary excision and primary or delayed suture will greatly reduce the incidence of the disease. The incubation period of the disease is usually about ten days, but may be as short as three days. So-called tardy tetanus may occur months after an injury if the wound is subsequently reopened. The shorter the incubation period before symptoms the greater will be the probable mortality. But little difference occurs in mortality whether the wound focus involves the lower or the upper extremity. The type of infection appears to vary in virulence in different years. In four different years between 1916 and 1921 the mortality varied from 14.3 to 71 per cent. in a comparable number of patients each year, and with the same general plan of treatment. When symptoms of the disease have appeared the attempt should be made to saturate the patient with antitoxin before fixation of toxin has occurred in the nerve cells of the spinal cord. This can best be accomplished by intraspinal and intravenous injections during the first three days of treatment; the total dosage, of which half should be given intraspinally, should approximate 125,000 units.

147. Laryngology and Otolaryngology in the Medical Curriculum.

A. LOGAN TURNER (*Journ. Laryngol. and Otol.*, July, 1922, p. 317) discusses the position of laryngology and otology in the medical curriculum of Great Britain, and the regulations at present governing such teaching in the different universities and medical corporations. He points out that it should always be borne in mind that the instruction is for the future general practitioner and not for those intending to specialize, and that therefore any detailed or elaborate banding of the subject suitable to post-graduate courses should be avoided.

The importance of certain clinical signs, not only in connexion with local diseases of the ear, nose, and throat, but in their relationship to general diseases, should be emphasized in order to enlarge the student's outlook upon general medicine rather than allow him to regard the instruction as being upon a "watertight" specialty. While there is little doubt but that these subjects will find a place in the new regulations under consideration by the General Medical Council it is advisable that each of the qualifying bodies should be permitted some scope in choosing that form of examination and instruction best suited to individual circumstances, each school being at liberty to advance its own scheme of education in its own way.

148. Arthroplasty for Ankylosis of Joints.

PETTI (*Lyon Chirurg. March-April, 1922*), in reviewing his results of the operation of arthroplasty, comes to the following conclusions. The modern operation enables one to create a joint of functional value equal to the normal joint, or one which gives complete satisfaction to the patient. With regard to indications—In cases of ankylosis of the temporo-maxillary joint, or bilateral ankylosis of the hip, or an elbow ankylosis in extension, there can be no doubt. Many of these joints after operation have allowed the patient to carry on laborious occupations; some were declared fit for military service after arthroplasty on the knee and elbow and served in the war. In ankylosis of the lower limb it is possible to obtain a firm and mobile joint. Petti considers the knee as a joint which gives complete satisfaction to the patient and surgeon after operation. The operative technique consists in using ample incisions to give free exposure. Enough bone is removed to leave an articular space which permits free movement; the ends of the bones are shaped to an appropriate form in each joint. It is absolutely essential to cover the bone ends with some substance which separates the osseous surfaces; Petti advises, and uses, free grafts of fascia lata. The mode of formation of the new joint surfaces agrees with that described by Murphy. The author drains the joint after operation. The secret of success depends on the judicious choice of cases, the careful technique at the operation, and in correct after-treatment. With regard to prognosis for each joint after operation he places them in the following order: elbow, knee, temporo-maxillary, and hip. Arthroplasty is not a dangerous operation; his mortality is under 2 per cent.

149. The Treatment of Gall Stones.

C. WESSEL (*Hospitalsidende*, April 26th and May 3rd, 1922, p. 15) reviews his experience of the treatment of gall stones in his hospital in the seven-year period 1914-20, in which 366 cases were observed. Of these, 200 were operated on, and in 56 per cent. the field of operation was sterile. The superiority of operative over conservative treatment has been borne in on him with increasing force, and he has come to the conclusion that an operation should be recommended as soon as the diagnosis has been made. The fact that only 200 out of the 366 cases were operated on was partly due to his not having been insistent enough on the need for operative treatment in the first years of the period under review. There were also cases in which, owing to advanced age or complications, an operation was contraindicated. But the most common reason for not operating was the patient's refusal to submit to an operation after acute pain had ceased. The author preserves the gall bladder whenever he can, and in only in 67 cases did he perform cholecystectomy; only in one out of 87 cholecystostomies did a fistula persist. Cholecystendysis was performed in 40 cases, in none of which did the author rue his choice of operation, and he recommends this procedure in uncomplicated cases.

150. Venous Thrombosis and Gastric Carcinoma.

MOORHEAD (*Irish Journ. Med. Science*, April, 1922), from recent experience in four cases, reviews the diagnostic importance, originally suggested by Troussseau in gastric carcinoma, of venous thrombosis as an early sign in malignant growths. In the first case—a labourer, aged 43—thrombosis of the internal jugular and axillary veins caused a painful swelling of the right side of the neck, and swelling of the right hand, with later involvement on the left side. Necropsy showed an unsuspected ulcerating cancer of the lesser curvature of the stomach, the peripheral venous thrombosis being the only prominent clinical symptom, and probably resulting from microbial invasion of the ulcerated growth. In the second case of gastric carcinoma thrombosis of the right femoral and saphenous veins occurred as a terminal symptom, practically every vein in the body becoming affected in turn during the last six weeks of life. In the third case thrombosis of the left subclavian and axillary veins preceded the discovery of an inoperable adenocarcinoma of both ovaries, while the fourth case was an example of general thrombosis in advanced malignant

cachexia, practically every superficial vein in the body, including those of the abdominal wall, becoming thrombosed. At autopsy the cancer was found to involve the pancreas, stomach, colon, liver, and the diaphragm, with thrombosis of both femoral veins extending up the inferior vena cava as far as the renal veins. Secondary growths, but no actual necrosis, were present in the walls of the vena cava, the lumen of which was constricted by the growth in the diaphragm. The cachexia of itself would seem to afford sufficient explanation of the condition in those cases in which the thrombosis was a late development, while in the early cases it is possible that tumour cells or organisms gain access to the blood stream; or, as Trousseau assumed, the condition may be accounted for by the existence of a special blood state favouring coagulation.

151. Megacolon.

The occurrence of idiopathic dilatation of the colon in childhood is relatively infrequent, but congenital megacolon in the adult is rare. FOWLER, DAVIDSON, and MELLON (*Surg., Gyn., and Obstet.*, May, 1922) report a case of this nature. The term "megacolon" is usually applied to the congenital and idiopathic condition which bears the name of Hirschsprung's disease. The symptomatology consists of obstinate constipation, marked distension, and active visible peristalsis, finally accompanied by signs of intestinal toxæmia, and usually resulting in early death. This active acute process begins at birth or soon after, and the dilatation and hypertrophy are present from the start. The typical picture appears to be that of an emaciated child with prominent abdomen; the dilated coils of intestine can be seen and masses felt within them. Enemata are followed by copious, offensive stools. X-ray pictures following a barium enema confirm the diagnosis. The disease often pursues a chronic course. Instances of acute obstruction of the redundant sigmoid, usually volvulus, have been reported. The diagnosis should be relatively simple, and a point in the diagnosis is that ascites does not accompany megacolon. In the treatment of megacolon, Ladd found to his surprise that the surgeons suggested medical treatment and the clinicians advised operation. Dietary regulations and measures designed to empty the bowels may be tried. In the advanced cases medical treatment merely accomplishes partial removal of the retained faeces at intervals. In these cases operation should be advised. Surgical treatment aims at removal of the functionless bowel and restoration of the intestinal continuity. Some surgeons favour a single-stage operation, others advocate a preliminary colostomy with secondary resection and anastomosis. The prognosis of megacolon is largely that of intercurrent diseases consequent on malnutrition. The theories regarding its etiology are numerous; the authors consider there is little clinical verification that it is a congenital pathological entity. The only congenital feature is a redundant sigmoid, and the anatomical arrangement invites obstruction at the recto-sigmoid junction, and kinks and valves have been demonstrated here.

OBSTETRICS AND GYNAECOLOGY.

152. Value of Low Cervical Caesarean Section.

J. B. DE LEE and E. L. CORNELL (*Journ. Amer. Med. Assoc.*, July 8th, 1922, p. 109) advocate low cervical Caesarean section (laparotrachelotomy) as the operation of choice, reserving the old classic operation for special aseptic and early cases. Through an abdominal incision an area of the cervix and lower uterine segment is exposed of sufficient size to permit delivery of the child without encroaching on that portion of the peritoneum which is opened in the higher operation. The advantages claimed are that the cervix and lower abdomen resist infection better, and the cervical wound, being unaffected by after-pains and active involution, is more at rest and heals better than the wound in the fundus. Since the wound in the cervix can be more perfectly closed and covered with fascia and peritoneum, there is relatively little danger of leakage of the lochia, and any spill at the time of operation is limited to a very small peritoneal area just above the pubes, which is known to resist infection well. The occurrence of adhesions, abdominal hernia, and the possibility of rupture of the scar in subsequent pregnancies are reduced to a minimum, and the operation can be performed after prolonged labour, and even in the presence of fever which contraindicates the higher operation. E. L. KING (*Ibid.*, p. 112), from a review of the end-results in 117 cases of abdominal Caesarean section, urges restriction rather than extension of the indications for its performance by greater pre-natal care, careful pelvimetry, early treatment of toxæmia, and better obstetrical teaching. Craniotomy or embryotomy on the dead baby should be undertaken more frequently, and the

Porro operation extended in infected cases, while laparotrachelotomy is becoming the operation of choice in the presence of infection.

153. Radio-therapeutic Drainage of the Pelvis for Cancer of the Uterus.

DAELS (*Gynéc. et Obstét.*, 1922, v. 5, p. 394) reported to the Société Belge de Gynécologie et Obstétrique the results of the treatment, introduced by him, of cancer of the cervix by radium "drainage" of the pelvis. This treatment consists in the extraperitoneal insertion into the pelvis of india-rubber tubes containing radium disposed at various points so as to affect the parametria and the pelvic lymphatic glands. Daels now makes the track for the tube by introducing, with the guidance of a finger, a graduated semicircular sound through an incision behind and external to the tuber ischii; it is passed upwards between the perineal and coccygeal portions of the levator ani and in front of the sacro-sciatic ligament, and withdrawn after being made to pass behind the great vessels through an incision external to the anterior superior spines. Spinal anaesthesia is preferred. The radiation, which is preceded by that of the primary growth, lasts, as a rule, for three days. The series recorded consists in 26 cases, of which 19 were frankly inoperable and 4 were post-operative recurrences. Of 4 cases in which the procedure was combined with hysterectomy (a combination which has now been abandoned) death ensued in 2 and convalescence was difficult in the others. Of the remaining 22 cases, 3 died at the sixth week (2 from pulmonary disease) and 1 on the seventh day; 5 had abscesses which became cured, 1 had a recto-vesical fistula, and 3 suffered from deep radium dermatitis. The cases are too recent for the more remote issue to be estimated critically, but include two instances of two years' cures of apparently hopeless cases. No immediate operative complication occurred in the 31 cases. P. PETIT-DUTAILLIS (*La Gynécologie*, April, 1922, p. 215) criticizes adversely the method of Daels, and enumerates the dangers which it entails of injury to important vessels and nerves. He suggests as an alternative introduction of a radio-active drain between the obturator internus and its aponeurosis, and points out that the external iliac glands may be irradiated, without opening the abdomen, by means of the classic access for ligation of the corresponding artery.

151. Is Perforation of the Living Fetus Ever Necessary?

O. KÜSTNER (*Zentralbl. f. Gynäk.*, June 4th, 1922, p. 882) believes that the introduction of extraperitoneal Caesarean section has rendered it unnecessary ever to perform craniotomy or embryotomy on a living child, even if auscultation of the foetal heart shows its existence to be severely endangered. In upwards of 200 Casarean sections made extraperitoneally in the antero-lateral aspect of the lower uterine segment, the mortality, in spite of the fact that nearly one-half of the patients showed pyrexia before operation, was less than 1 per cent. Accordingly, Küstner criticizes the attitude of those who, while granting the extraperitoneal an equal or superior place to that of the classical operation, hesitate to perform the former in patients who apparently show signs of severe infection. He points out that it is difficult clinically to estimate the chances of survival of a foetus whose life appears to be threatened; that clinical judgement, as well as that made by searching for the presence of various streptococci, regarding the extreme severity of maternal infections is in the highest degree uncertain; and that destructive operations are attended with a danger of sepsis and with a mortality which are at least equal to those connected with extraperitoneal Caesarean section. The prognosis of the accidental injuries, which may occasionally accrue to the urinary tract during low hysterotomy, is good.

155. Disappearance of Orthostatic Albuminuria in Pregnancy.

E. SYLVEST (*Ugeskrift for Læger*, May 25th, 1922, p. 563) has frequently examined for albumin the urine of a woman, aged 30, since she was 10 years old. At this age albumin was found in the urine, but casts were never demonstrable, and the morning urine never contained albumin. At the age of 19, in the second month of her first pregnancy, the urine was free from albumin, and it remained so throughout the rest of the pregnancy. After labour the albumin returned in the evening urine. The second pregnancy, at the age of 23, was again associated with complete freedom from albuminuria. Just before she became pregnant for the third time the evening urine contained albumin, but five weeks after her last menstruation no albumin could be found. Though there was no other sign of pregnancy it was diagnosed on the strength of the disappearance of the albuminuria, and this diagnosis proved correct. After the termination of this pregnancy the urine continued to be free from albumin.

156. Intestinal Obstruction during Pregnancy.

ACCORDING to M. VAUTRIN (*La Gynécologie*, April, 1922, p. 193), intestinal obstruction occurring during pregnancy, in the absence of the usual causes encountered apart from gestation, is most frequent among multiparous subjects of chronic constipation who suffer from viscerophtosis. The site of the occlusion is almost invariably the pelvic colon in the neighborhood of the attachment of the infundibulo-pelvic ligament; the upward enlargement of the gravid uterus produces tension of the infundibulo-pelvic ligament and angulation of the pelvic colon, and the same enlargement, together with the rotation which the uterus undergoes during pregnancy, may lead at the same time to a certain degree of axial rotation of the colon. An accumulation of faeces, together with the external compression exerted by the pregnant uterus, serves to render the chronic obstruction acute. In many instances treatment by purges and enemata suffices to ameliorate the obstruction, which returns in subsequent pregnancies, but in some cases operation is necessary; this should consist simply in draining the caecum, if possible through the opening of the excised appendix. Vautrin relates the history of three personal cases which support the explanation advanced above of the pathogenesis of the intestinal obstruction of pregnancy; a similar explanation has been put forward by Cunéo, Seucert, and Okunezye.

PATHOLOGY.

157. The Metabolization of the Blood Elements.

H. M. WOODCOCK (*Journ. Royal Army Med. Corps*, June-July, 1922) considers that not only the macrophages, but also many other types of tissue cell are capable of metabolizing blood elements in order to elaborate by the utilization of the formed blood elements (mainly the erythrocytes) various substances, such as secretions or excretions, which are requisite for the welfare of the body as a whole. He uses the term "haemetabolism" for the metabolization of the blood elements, whether it occurs intracellularly or extracellularly; and "haematophagy" for the actual ingestion of the blood cells by the tissue cells. From a study of the formation of colloid in the thyroid gland, as observed in adenoma, the author concludes that the small masses of colloid seen in sections are formed by the metabolization of the red corpuscles, this transformation being effected by means of a ferment secreted by the nucleus of the epithelial cells in immediate relation. The corpuscles are metabolized whilst they are still actually in the minute capillaries, the ferment either passing through the delicate wall, or probably dissolving the wall itself. The haemoglobin is not split up into two separate compounds but metabolized into one uniform material, colloid, which probably contains all the haemoglobin in the form of another complex organic compound. In studying the condition as found in the normal thyroid the author demonstrated that the colloid secretion contains iron, similar to that of the haemoglobin of the red blood corpuscles, whereas the epithelial cells of the thyroid do not appear to contain any iron. As a result of changes in blood pressure the red corpuscles pass by diapedesis either through or between the epithelial cells, into the lumen of the follicle, becoming changed into a substance homogeneous in appearance but not yet showing the finely granular character of the surrounding colloid. By appropriate staining the evolution of this substance into normal colloid may be determined. A similar course of haemetabolism may take place between the acini in the interfollicular zone and not in the lumen. The colloid contained within the lumen of the acinus escapes into the lymph channels probably through the disintegration of the epithelial wall in places where the lining cells become effete and die. In addition to the colloid, formed by the metabolization of the red cells, there is also present in the lumen of the follicle some liquid substance which has been secreted by the epithelial cells themselves, but there is no evidence of the transformation of this secretion into colloid, and such a secretion only takes place into a lumen already containing formed colloid. Thus the conception is false that red blood corpuscles serve only to bring oxygen to the tissues; they are concerned also in the production of vitally important secretions. In studying the melanin pigment of the skin the author has observed the occurrence of unaltered red corpuscles in the epithelial cells of the normal skin of the scalp, and puts forward the hypothesis that these red cells are digested by some ferment of nuclear origin with the production of melanin pigment. If tissue cells are capable of assimilating nourishment from the metabolization of other cells, then it is easy to understand how in malignant disease certain individual cells might assimilate such nourishment for their own independent use and inco-ordinated growth and reproduction, thus reverting to the state of single-celled animals, and devour and digest red cells, leucocytes, and other tissue cells.

153. Vaccination against Cholera by the Oral Method.

AN attempt has been made by MASAKI (*Ann. de l'Inst. Pasteur*, May, 1922) to devise an effective method for the immunization of animals against cholera. If the vibrio cholerae be injected in suitable doses intraperitoneally, subcutaneously, or intravenously into a guinea-pig the animal dies a few hours later; bacteriological examination *post mortem* shows in each case an abundance of the organisms in the small and large intestines, while the blood and the peritoneal fluid, as a rule, are sterile. It is clear, then, that, however introduced into the body, the vibrios are excreted into the gut. The problem is to render the cells of the intestinal mucosa insensitive to the action of the cholera toxin. Simple oral ingestion of either dead or living vibrios fails to immunize the animals, nor do any symptoms of illness occur. But if the animal be previously given bile by the mouth the cells are so altered as to become more or less permeable to the cholera toxin secreted by the organisms, and consequently allow a certain amount to enter the blood stream. If the sensitization be carefully controlled and the subsequent dose of living vibrios be likewise regulated strictly it is possible—at any rate in the rabbit—to render the animal refractory to a dose of living organisms injected intravenously. In such a case the blood can be shown to be free from protective antibodies, so that it would appear to be a local cellular immunity of the intestinal epithelium which is responsible for the state of insensitiveness thus engendered.

159. The Oxydase Reaction.

SEVERAL different methods for demonstrating the presence of peroxidase in the white cells of the blood have been tried—none with entire success. J. SABRAZIS (*Gaz. hebdom. Sci. Méd. de Bordeaux*, July 9th, 1922, p. 331), who has been working on the subject, has come to regard the following technique as being the most satisfactory. An ordinary blood film—air dried—is covered with a 0.5 per cent. alcoholic solution of benzidine, to which a few drops of hydrogen peroxide are added. After allowing the reagent to act for five to twelve minutes the slide is washed in distilled water, which is then shaken off. The film is finally placed face downwards on a cover-slip flooded with a 0.2 per cent. solution of methylene-blue, reversed, and examined under the microscope in the moist condition. Using this technique, he has paid particular attention to the mononuclear leucocytes. Whether or no the blue oxydase reaction is given seems to depend on the size of the cell. The smaller ones, with nuclei which are oval or only slightly indented, fail to react, while the larger cells with multilobate nuclei usually react in a positive manner. The test, varying as it does considerably in its intensity, is obviously of little use in the classification of these cells. In cases of chronic myelæmia the neutrophils and eosinophile myelocytes give a positive reaction, just as do the polymorphonuclear and eosinophile leucocytes; on the other hand, the basophile myelocytes and the myeloblasts are negative in their response.

160. A New Typhus Organism.

BELAI (*Wien. Woch.*, April 20th, 1922) gives an account of an organism described by Schestopal under the name of "*Spirochaeta emiliae* Schestopal," which is found in the blood of the roseolae or petechiae of typhus patients. It is present in all stages of the disease, but is most likely to be met with in roseolae two or three days old. The organism is a spirochaete varying in length from a quarter to five times the diameter of a red corpuscle. It is thinner than a red corpuscle, and is about the size of *Spirochaeta pallida*, but has more numerous and smaller spirals. Almost all the spirochaetes in the field are attached to red corpuscles. They show active movements which last for about thirty-six hours after the blood has been taken.

161. Relationship between the Leucocytes of Venous and Capillary Blood.

THE question asked by MIRONESCO (*C. R. Soc. Biologie*, June 3rd, 1922) is: What is the meaning of a leucocytosis? Is there an actual new formation of white cells in the haematopoietic organs of the body, or is there merely a redistribution of them in the blood? In answer to this he quotes cases in which the number of leucocytes in the capillary blood was considerably in excess of that found in the venous blood removed from the basilic vein, and other cases in which the inverse relationship was established. Similarly in the rabbit distinct differences have been noticed in the leucocyte count taken from the capillary blood, from the inferior vena cava, and from the heart. Further, it is known that simple changes in posture may bring about an alteration in the blood picture of the patient. From all these facts he concludes that in a leucocytosis it is not a new formation of cells, but a redistribution of the cells already in existence, which is involved.

WHAT DUNLOP CORD TYRES HAVE DONE

From Capt. G. EGERTON PEARCE, Chagford, Devon.

"In October last I had Dunlop Cord Tyres fitted to my 25 h.p. Vauxhall car. I drove the car to the South of France, carrying a large amount of luggage and three adult passengers. I used the car almost every day for six months and came home via the High Alps. The journey was made in the worst of weather, but we arrived safely back in Devon with the same set of tyres with which we went away. The tyres are very little worn although the mileage is fully 6,000."

From S. F. EDGE, Esq., Ditchling, Sussex.

"I thought it only right to let you know how very successful the Dunlop Cord Tyres were which you supplied me with for my six cylinder A.C. car which was entered recently at Brooklands, and gained such a big series of records from 2 to 12 hours inclusive, averaging for 12 hours over 70 miles an hour. I believe they stand with the unique record of having run a greater distance at 70 miles an hour than any set of tyres in the world have ever done."

From H. G. POPE, Esq., Maldenhead.

"I used your Cord Tyres on my G.W.K. car in the Scottish Six Days Trial, and obtained the best possible award, a Gold Medal. The same set of tyres were used in the London-Land's Edd Trial, in which I attribute my successes to the excellent gripping properties of your tyres."

From FRANK SEARLE, Esq., Managing Director, Daimler Hire Ltd., London, S.W.7.

"I should like to put on record the really wonderful results we are getting with your Dunlop Cord Tyres. Considering that our fleet consists of 250 30 h.p. landaulettes and our mileage in the summer approaches five hundred thousand miles a month (all of which is done on Dunlops) we are in a position to appreciate good value for money in tyres."

From a User at Alderley Edge, Cheshire.

"In May, 1921, I purchased a six cylinder Armstrong-Siddeley car fitted with your Cord Tyres. I have done exactly 10,000 miles running, and have had no trouble whatsoever, no punctures or bursts, and the tyres still look good for two or three thousand more miles."

From R. G. JACKSON, Esq., Maldenhead.

"I used your Cord Tyres on the London-Land's Trial, the tyres giving the utmost satisfaction. I have not had a puncture since they were originally fitted, neither have the tyres needed to be touched in any way."

From W. MORRISON, Esq., Loch Assynt.

"I am glad to say that your Magnum Cords are really good and I am having splendid service out of them on Albion and Ford cars."

From A. R. HUNTER, Esq., Workson.

"I am now absolutely convinced that there is nothing better in the tyre world than the Dunlop Cord."

From F. J. CAFFYN, Esq., Caffyns Ltd., Eastbourne.

"I am still driving on the original four Dunlop Cords, although I have now exceeded 9,000 miles. Three of these tyres have not been re-inflated since fitted."

From W. H. BOWATER, Esq., Birmingham.

"I have been a user of your tyres for many years, and thought it would be interesting to you to know the mileage done by the last four tyres on my car. The Tyres are Cord, size 820 x 120, and are run on a Wolseley 20 h.p. six cylinder limousine.

Tyre No. 18184 Mileage 15,987 miles.

" " 18114 " 15,096 "

" " 17137 " 18,735 "

" " 18062 " 17,697 "

I have a careful record kept of all my tyres, and if you would like to verify the mileage, I shall be very pleased for you to do so."

From JAMES FAIRLIE, Esq., Falkirk.

"I have on my Moon car two Dunlop Cord Tyres which have reached the 14,000 mile mark and are still going strong... two others have done over 5,000 each and look quite fresh."

TRADE MARK.

HOW THE "NO TROUBLE" TYRE JUSTIFIES ITS NAME

To obtain the best results from any cover, give it the unfailing support of a Dunlop tube.

The "CURTIS" ABDOMINAL SUPPORT

A Success! And Why?

CONSTRUCTION

The ONLY Abdominal Support that will remain permanently in position on any shape of abdomen *without* the use of perineal bands or similar contrivances.

A somewhat sweeping statement, but one that we have justified. The reason is simple! The support is *not dependent on a circumferential pressure* but on a direct anterior posterior pressure which leaves the hips quite free.

TYPHOID FLY or better known as HOUSE FLY

To the Medical Profession and the Public.

The Wonderful Fly and Wasp Trap

SOLD ALL OVER THE WORLD.

This is the only Fly Trap constructed on scientific principles, as it controls the fly by working along the lines of its well-known habits.

As a primary means of eliminating the fly, its efficiency has been proven on a more extensive scale than ever undertaken before in this or any other country.

There are but two ways of getting rid of flies, one to destroy all filth; the other to destroy the fly before it lays its eggs. Destroying all filth is not practical, destroying the fly is. **Dead flies do not lay eggs.** If we kill this crop we destroy those of the future. **A fly will lay 492 eggs.** We can catch it before it lays any. The fly does not lay until it is 10 or more days old. Catch it before it begins to lay and we do not have any more. Thousands testify that this has been done with this wonderful Fly-Trap.

At reduced price of 12/6 (for Great Britain, including packing and postage)

Abroad 2/6 extra. (G.S.'s must accompany order).

See Article B.M.J., August 23rd, 1921, page 304.

Note.—Placed outside give excellent results. Two million flies were caught in this trap in two days. 100,000 sold to the American Government in 1918. Indispensable to Municipalities, Hospitals, Butchers, Dairy-men, Restaurants, Public, and every Household, and to Fruit Growers to eliminate wasps.

THE

British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, SEPTEMBER 2ND, 1922.

EDUCATIONAL NUMBER, SESSION 1922-1923.

THE TRAINING OF THE MEDICAL STUDENT.

BY

THE RIGHT HON. SIR CLIFFORD ALLBUTT, K.C.B., M.D., LL.D., D.Sc., F.R.S.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

IT is the desire of the Editor of the JOURNAL that the Educational Number for the next academical year should begin with some general reflections on Medical Education as it now is; this task, a difficult task indeed, he has laid upon me. At the present time the many inquiries, controversies, and opinions on the subject, like a multitude of remedies for a disease, do but prove how unsettled are the ideas and the methods of this education, how variable the conditions of it, how vacillating our values of its means and ends. We lament the burden laid upon the student, yet each reformer begs leave to add to the pile.

MAIN PRINCIPLES.

In undertaking to try to unravel so tangled a subject we must endeavour to lay hold on some main principles. Three principles of all professional education seem to be fundamental: first, to secure a good general education; secondly, a good scientific education; thirdly, a good technical education. The period of each of these makes by itself a large demand; all three of them together a very large one; indeed, we are but too well aware that a complete general and medical education occupies already more than a quarter of the student's life! Before he can enter upon his career a quarter of his life is gone: let us think of that!

DIVERSITY OF INDIVIDUAL GIFTS.

Speaking generally, and within civil societies, individuals vary more than circumstances; in other words, out of similar circumstances individuals draw different advantages; so that although up to a certain period of life education may be laid out on broad indiscriminate lines proper for all young persons, yet for adolescents by rapid degrees it must become more and more diverse and several, dividing itself into the education of classes, of groups, and of individuals. A uniform development of all the faculties can pertain only to the earlier stages even of school life; the abilities of the older boy, as he matures, will, if he is worth much, betray some bias, in one way or another.*

ACADEMIC & TECHNICAL TRAINING.

The human child is born with potencies and capacities rather than with efficient abilities; he does not take up an independent life almost from birth, as the

chicken does. In the beginning even the very instruments of sense, action, and thought are rudimentary and must be developed before the mind can enter upon its proper functions. Not till then can the several courses of learning be commenced; and in Man each of these again is deep and slow, and the conditions manifold and intricate. Dexterity, language, philosophy, science, technical furniture, each of these, if given its own way, might arrogate the devotion of a lifetime. Some compromises then—some trenchant compromises, must be made, and some innate capacities sacrificed. Sad to say, the all of each of us is not wanted. How then in medical education is some measure of accommodation to be made without rejecting altogether the fertilizing virtues of each element? Shall we not answer that even in some of the ancillary professional subjects we must compromise by illustrating and instilling principles, with the sacrifice of all but the most significant detail? In part perhaps we must do even more, and cut away from certain of the preliminary subjects even the principles of some divisions which, precious as they may be, are not immediately concerned with the practice of Medicine. In school mathematics, for instance, parts, such as logarithms and the calculus, are usually omitted; so again in some departments of physics experiment might be carried so far only as to illuminate the broader principles, and to implant a due respect for the universality and exactness of this department of science. In chemistry the medical student must needs go farther and deeper; both larger and lesser principles must be clothed more richly with detail; yet even here, for the ordinary curriculum, some parts may be taken more in principle than in detail: the average student need not undertake it on the scale of a "pure science." In the final courses of Medicine proper, instruction must be thorough and comprehensive, both in principle and detail. The ordinary student then may content himself with the principles of certain departments of study, but on condition that he learns a few subjects thoroughly—those that bear directly upon his profession; and these not for their practical use only, obligatory as this is, but also for intimate training in accuracy of observation and thought; that he may be forced into conflict with the rigour and complexity of natural laws and events. This discipline the ordinary student will find first in anatomy and physiology.

* See my little book on *Professional Education* (Macmillan, 1925).

THE SCIENTIFIC MAN AND THE "PRACTICAL" MAN.

But how is even this economical course to be distributed? I have said before, and unwillingly repeat the opinion, that we may have to provide frankly for two classes of medical men: for a class of accomplished physicians (I refuse to divide surgeons from physicians), or medical scientists such as pathologists, and another class of dexterous resourceful kindly practitioners, all-round men well equipped with sound doctrine, but without pretensions to breadth or depth, to research or erudition. This class we see around us already, a class of trustworthy competent family physicians who in difficulty can call to their aid colleagues more intimately conversant with scientific theory, or with one or more special departments of medicine. Such a primary division, both of men and function, is represented by Diploma and University degree respectively. In answer to the daily needs of social life, and the various endowments of individuals, we see the "practical man," doct, shrewd, unanalytic, untheoretic, working with the reflective, learned, widely or specially experienced colleague. The one is stationary, and his invaluable practical skill and resource largely die with him; the other is of those who extend the boundaries of knowledge. If we can educate the men of the first kind in five years, to the studies and training of those of the second kind we must add half as long a time again. Not only so, but as from boyhood talent and capacity promise to be stronger and richer, the plan of education should be the longer, wider, and more arduous. Of geniuses I do not speak; they transcend all our reckonings.

UNIVERSITY v. TECHNICAL SCHOOL.

Not for all students then, even students of some promise, may it be worth while to take a university course with its greater cost in time and money; some very valuable members of our profession have a turn for craft rather than for intellectual study. The two varieties of boy can be discerned at school, and severally provided for. Both varieties would be the better for the amenities of a university education, even if one of them aimed at no academical distinction; but means may be scanty, and for the bookless boy no scholarships available. What must not happen is the lowering in any degree of the university standard to accommodate the less intellectual or less fortunate students. In Cambridge we often meet with students who had better not have taken a university course, but been content with a diploma, such as that of the "Conjoint Board."

LACK OF GENERAL EDUCATION.

Not only so, but many, most perhaps, of these undergraduates who drag through our course with burden to themselves and to us, fail not so much in natural talent as by lack of that general education which, if lost in boyhood, can hardly be recovered later. The schools are improving, and improvement they certainly need. Secondary education has been shortsighted, ill planned, and dislocated: dislocated especially in the neglect of English for a factitious classicism; ill planned inasmuch as abstractions—impalpable to the boy—have been substituted for the concrete, book-learning for practice. No boy ever learnt cricket from a book, but many cricketers would enjoy a demonstration of the mathematics and mechanics of their game. At last, in secondary schools, it is now recognized that science must be a part of every boy's education; in Cambridge therefore we expect all poll men to pass the "Preliminary Scientific." The science brought up from the schools is far better than it was; but of his own language the boy is more ignorant than ever; he is worse in so far as he brings with him a second-rate journalese instead of that spontaneous vernacular formerly his own.

ALL TEACHING BASED ON PRACTICE.

The innermost need of practice, to develop the educational tree in root and stem, should guide all our methods. I have said elsewhere that in its exercise the hand seems to achieve a little more than its mental message; it explores, and in each new use or adventure discovers a somewhat wider range of function and choice than the will had dictated.* "Things outward draw the inward quality after them." Without these tentative excursions it seems that development of faculty, and of its instruments, either does not occur, or occurs in much less measure and substance. The boy, bewildered by a table of triangles and ciphers, would be delighted to survey the back garden. Whether in medicine, law, or religion, our individualist folk desire "applied" before "pure" intellect.

THE DIPLOMA.

It is for this reason that I think the diploma student would do best to begin his first year's medical course with anatomy. By this study the hand, eye, and mind are trained together; and the minute precision, symmetrical complexity, and exquisite adaptation of every part in a consummate whole call forth a like perfection of observation and record. Upon this, as sure foundation, can be built some wider conceptions of morphology, evolution, and physiological function; anatomy and physiology being studied as two aspects of one subject.

THE UNIVERSITY DEGREE.

For the larger or university course, the student with ampler means in time and money will provide himself with a larger groundwork; he will give time first to the study of Physics; especially to mechanics, optics, molecular processes—such as osmosis, catalysis, interface actions, and so on—and electricity; studies essential to comprehension of life, of records, of functions, and of therapeutics; if these studies are to be carried to university standard. And so on for the later subjects, for biochemistry, pharmacology, and the rest. But this extended course means from six and a half to seven years' pupillage.

BAD SECONDARY EDUCATION.

But whether the student undertake the shorter utilitarian course, or the longer academic, it is essential that he should be equipped with a good general education, and I repeat that it is here that we find our pupils so sadly wanting. A boy learns Latin, let us say for ten years, yet at the university he betrays at once his innocence of the derivation and pronunciation of the simplest technical terms of his professional studies. Not that this matters essentially; a good school education can be given without either Latin or Greek; the undergraduate may know nothing about Plato, Aristotle, Thucydides, or even Hippocrates, but he may know something of Newton, of Locke, of Hume, and of Mill: still as we know that "Classics" are taught after a fashion at school, and that modern philosophy and English literature are not, we suspect that, if he hardly knows the names of the great ancients, neither is he conversant with great ideas, or with history in any age; not even in his own. Can we be surprised then that an eminent scientific teacher recently declared "that education and culture need not be associated with bygone civilizations"? Even on the science side, what would ethnologists, psychologists, nay even anatomists, say to that? But it is true that modern languages and literature, treated seriously, can form a sufficient training for a profession; at the least let the schoolboy be taught his own language: now he almost always leaves school barbarous, whether in the use of his own tongue or in the knowledge of English history, scientific or literary.

* C. A., loc. cit., p. 18.

THE IMAGINATION, ITS KINDS.

We must lay the more stress upon general education as we see that intensity of particular study, for which I suppose we must use the ungainly word "specialization," must be the lot more or less of all of us; of it I will speak presently. But it is of the utmost importance, before this contraction of field comes about, that the youth should be trained in his imagination, a faculty which at school lies almost dormant. Yet the intellect and the imagination are the two chief coefficients of mind. Now the imagination is of two kinds: the creative and the abstractive; as of Dante and of Galileo, as of Hardy and of Darwin; the one potent in art, the other in science. As the abstractive imagination will find more nurture in a scientific calling, for these boys perhaps the creative should be nourished at school on the stories of great men, great events, and great thoughts; whether "classical" or "modern." How much more fertile is the mind endowed with imagination of either kind we see in every laboratory. Not only so, but those who have less of this animating and constructive endowment need at least so much culture as to open their eyes to the best. The second-rate comes and goes with us continually; it rises and falls, is courted and neglected; the first-rate rises slowly, and needs some inspiration to conceive it, but it abides; surely withstanding not only the treachery or indifference of men but fire also, the moth, and the edge of the sword.

Even analysis has its relation to form; almost as soon as we can observe carefully and accurately we must begin to select, and as we select we depend on the imagination for tentative concepts, and for some vision or order. For instance, let us remember that diseases are not "morbid entities" but states of many persons, multitudinous states, no two alike, but of which we form general concepts; there is no such thing ("entity"), for example, as typhoid fever—which is a concept, a necessary figment of the imagination. Again, in Medicine, we have continually to act on probabilities, probabilities divined by observation and sagacity; and we shall judge well or ill as we have built our concepts well or ill; that is, as the harvest of eye and imagination is rich or poor, crude or cultivated. If the imagination is animating and enlightened so the subordinate faculties will be led forth, and take each its own place. Now this quality in both kinds depends on some occupation with both the matter and the manner of great authors, literary and scientific; that is, on "General Education."

21

SPECIALISATION.

The harm then of "specialisation," the scorn of "the school of infinitesimal research," lies not in Nature but in narrowness of the student's mind, be he old or young. Enter into the realm of nature by whatsoever gate you please, you will find yourself in the presence of infinity. If the mind of the student is dwarfed it is because of his short sight, not for lack of horizons. If, on entering into practice, the student qualifies as a "specialist" by falling into ignorance of all else, his pretension is vain; if he is to look his problems fully and intelligently in the face, he must take up the all else into that special study. Unless perhaps in respect of a few clever devices of handicraft, this means an academic education. A critical and flexible judgement comes of a familiarity with, and an appreciation of, the relative values of ideas, present and past. The examination candidate begs his coach to tell him how to answer, but not for heaven's sake to explain the reasons of the answer. He wants knowledge which can be sawn into planks for the examination platform. The harm of specialism lies then not in a limited field, this it is not; no side or adit of nature is limited; but because the specialism is reached not by carrying the whole into the part, but by stopping short at the turn.

For this reason in Cambridge we have declined to grant Diplomas on subjects which belong to the ordinary course of instruction; such as diseases of the eye, tuberculosis, and so forth; with us they are restricted to subjects lying outside the ordinary curriculum, such as Tropical Medicine, Public Health, or Mental Diseases.

EXAMINATIONS.

To close this chapter without some allusion to *Examinations* would be to forget a very serious part of the burden of Medical Education. How to secure the unquestionable gains of these tests without the evils of them is a dilemma of which no one as yet has ventured to propose a solution. The question is, How much of an evil may it be necessary to tolerate? The three chief Examinations, with some three more subordinate, impose a great strain on the student by concentrating into a few severe and intense trials at long intervals tests which might and ought to be more gradual and continuous, and better integrated with regular work. To keep up a number of subjects at *examination pitch*, as a conjuror keeps many balls in the air, is a very exacting effort. The harass and anxiety of them waste some of the energy which ought to be devoted to calm and assiduous work; to be returned from one of them means also a serious setback in time and expense. This is not the place to offer an alternative method, even were so difficult an undertaking possible for me. But the relief will have to be made by throwing more responsibility on the teachers for frequent and formal class examinations, by requiring the students' notebooks from laboratory and ward to be submitted under proper guarantees to the qualifying body; and so forth. In Cambridge, more than once, we have suggested to outside teachers that the clinical notebooks of the students should be submitted to us, but the answer is that at present there is no organization to carry out such a system.

RECIPROCITY IN MEDICAL SCHOOLS.

In conclusion I desire to ask the hospital schools in London to consider the great advantage, both to themselves and to their students, of free access from one school to another; of an intercollegiate reciprocity. Why should not a student of one school, duly accredited by card, be permitted freely to visit the clinics or lectures of another? The loyalty of a student to his own hospital would not be sapped by availing himself occasionally of certain courses of another; particularly in special subjects such as cardiology, neurology, tuberculosis, and so on. Do not let us flatter ourselves: his loyalty depends more on the school football than on our lectures. The fee difficulty could easily be arranged at a Clearing Office. By such free opportunities the active and competent teachers would be encouraged, and perhaps the natural powers of some of them aroused; the good teacher would draw larger classes, the less capable would be amended, or lose artificial protection. The student on his side would have his views enlarged, and his mind furnished, by the various gifts of various teachers. Each school has its strong points, each its incidental advantages. *Non omnia possumus omnes*. Moreover, there are certain subjects, such as the History of Medicine for example, which cannot, or need not, be comprehended in every school, but, if established on the open system in one or two, would do much to further medical culture.

But, after all our preparations, we have to counsel our pupils that "It is impossible you should take true root but by the fair weather that you make yourself; it is needful that you frame the season for your own harvest."

THE PLACE OF PHARMACOLOGY IN THE MEDICAL CURRICULUM.

W. E. DIXON, M.A., M.D., F.R.S.,

Reader in Pharmacology, University of Cambridge.

MEDICINE has as its ultimate aim the prevention or cure of disease: the practical aspect so far dominates every other that not infrequently it is termed the healing art; indeed, it is difficult to think of medicine as other than something connected with treatment. Nor is it necessary to refer back to many decades of medical history to discover that it was then nothing but a healing art, a system of recipes, of panaceas, of rituals, sometimes priestly, sometimes philosophic, but all devised to combat the symptoms and signs of ill health.

In their beginnings physiology and pathology, which now form the scientific basis of medicine, were merely natural history, their facts were empirical, they were independent entities set apart from other knowledge, for a science is independent in proportion as it is imperfect. When these sciences passed from simple observation to deduction and experiment they naturally attracted the more eager minds in medicine, and the text of the writings of the nineteenth century deals with changes in structure and function. Treatment was neglected, the old shibboleths were discarded, and there was nothing with which to replace them. One important result of this open scepticism of the value of treatment was the growth of systems of treatment, like homeopathy, and the rush of an over credulous public to irregular practitioners. The textbooks of the period told with considerable precision what was happening in the body during disease and what was likely to happen, but no word as to how to prevent it; treatment was dismissed in a few curt lines. This state of affairs was unavoidable; there was no specific treatment, there was no science of treatment, for such a science could only come into existence when physiology and pathology had reached some degree of precision. The science of treatment or pharmacology is therefore relatively new; it includes knowledge of all kinds dealing with the treatment of disease or alleviation of suffering. It is the climax of physiology and pathology, devised to subserve a practical end, and forms an important part of the great biological topic of the influence of conditions on the living organism.

To state that the future of medicine lies in pharmacology may sound fanciful, but it is certain that the most hopeful of all signs of the progress of medicine of to-day is to be found in the progress of the science of treatment. Few drugs now exist the mode of action of which is not understood, and the goal is not so far distant when it will be possible to introduce into the animal economy a factor which will exaggerate or retard the function of any tissue or collection of cells in the body, leaving the others unaffected.

At one time hopes ran high that the chemical structure of the molecule might indicate action, an idea by no means new since Paracelsus directed chemistry into new courses by stating, "The real object of chemistry is not to make gold but to prepare medicines." During the last fifty years most laborious researches have been conducted to this end, so to modify the molecule that it may conform to some required action. But the mystery remains as mighty as ever. It is not improbable that subtle energy factors binding the molecule—factors not displayed in a formula—control the action: certain it is that drug action is not determined directly by chemical combination with body constituents, but rather by delicate physical processes such as those of adsorption, solution, and surface tension. Chemists have not yet determined the requirements of the molecule even for the production of colour. On the other hand, slight alteration of a molecule already complicated and with a known action has led to the production of many useful compounds, and not infrequently we may foresee the type of action which will occur under such special conditions. Considerations of this nature have led to the synthesis of the new local anaesthetics, natural have led to the synthesis of the new local anaesthetics, antiseptics, antipyretics, diuretics, tropane, and many others.

The general outlook and significance of drug therapy was led into new channels when it was revealed that the animal body elaborates its own drugs, stores them generally at the seat of formation, and doses them out to the tissues to meet the needs of the economy. Some of these drugs are of the

nature of true crystalline alkaloids; thus adrenaline is formed in the suprarenal glands and thyroxine in the thyroid. Some others, the properties of which we know something, have yet to be prepared in a pure form: for example, the ovary and pituitary body each contains some drug invaluable to the animal. Pituitary extract of animals exerts a wonderful tonic action on the uterus: for several years the physician has employed this substance in his clinics to contract the uterus. But now it is revealed to us that pituitrin manufactured in nature's laboratory is the drug used by nature to contract the uterus. Ovarian conditions determine its liberation; the ovarian drug is set free in the circulation, it causes the liberation of pituitrin, and the uterus is affected. Can a more convincing example be offered of the inner meaning of drug actions? The normal functions of the body are regulated at least partly by these natural drugs, and it has been suggested, not without reasons, that all functionings are of this nature and that the object of a nerve supply is to localize the liberation of the active drug in the neighbourhood of the nerve terminations.

The patients whom the physician of to-day is called upon to treat may be divided into two groups: (1) Those suffering from active disease, excess or deficiency of one of the natural alkaloids, poisoning by improper food, or poisoning by micro-organisms or their products. (2) Those whose tissues are functioning badly because of scars left by previous active disease; this group includes many paralyses, joint troubles, and cardiac disease. To cure an old scar is difficult, though much may be done to render the patient's life tolerable and useful: the pity is that the scar stage is ever reached. It is with the first group that the hopes of medicine and the future of pharmacology principally lie. Already it is possible in many instances to destroy the causal agent of some diseases, but not, we believe, by the direct action of the drug on the causal agent. The organic compounds of arsenic have no marked effect on the spirochaetes of syphilis in the test tube, but they destroy them in the body; ointment does not kill the amoebae of tropical dysentery except in the human body. A still later production of the laboratory is a derivative of trypan-blue which destroys trypanosomes in the body of both man and animals: the introduction of this substance into medicine initiates a new era in trypanosomiasis and promises the opening up of vast tracts of tropical Africa now prohibited to man by sleeping sickness and to animals by the bite of the tsetse fly (*nagana*), and by other forms of trypanosome disease. The attack by drugs on bacterial diseases lies in the future: ethyl-hydrocuproine administered to men in appropriate doses destroys the micro-organisms causing pneumonia, and even the drawn blood of patients so dosed will destroy those pneumococci. This is as yet our only instance of specific drug therapy in acute general bacterial disease, but it proves that the problem is not insoluble.

Those facts show that pharmacology cannot be taught with any value until the principles of physiology have been attained; also, so intimately is it concerned with pathological processes and clinical medicine that to divorce it from them is to lose much of its value. Taught as a science complete in itself, pharmacology becomes all but valueless to the student of medicine. Its proper place in the curriculum is during the first year of clinical studies, when laboratory work can be supplemented by clinical demonstrations. With general pathology and bacteriology it should form the connecting link between the science and art of medicine; such an arrangement might do much to destroy a system of watertight compartments, for each branch of medicine is mutually dependent on the others.

Nevertheless, science alone does not make the good physician; too great stress can hardly be placed on the fact that it is not the disease but the patient who is treated. Sympathy, understanding, a knowledge of life and men, are of no mean value to those who aspire to treat the sick, and I for one should regret the day when my revered juniors, imbued with all the sciences, treat their patients with no other considerations than those laid down in the manuals of experimental pharmacology.

THE PROFESSION OF MEDICINE.

THE approach of October reminds medical men and women that the opening of a new Session is at hand, and for long past the annual Educational Number of the *BRITISH MEDICAL JOURNAL* has appeared at this time of year. Our brief remarks here, on the profession of medicine, are addressed more particularly to intending students and their parents. A few notes also are added on current matters affecting professional study and practice, which may interest those who think of devoting their lives to medicine, and help them to judge of their fitness for the calling and of the prospects it holds out.

While our present issue is largely a guide to the steps that must be taken in order to become a legally qualified practitioner of medicine, certain parts are written for younger members of the profession who may be in doubt as to the path in medicine they should choose as a career. The information given under these two main heads follows the customary lines; but some of the sections have been much amplified this year, and several wholly new features are included. Thus we are fortunate in having persuaded the doyen of British Medicine, Sir CLIFFORD ALLBUTT, to contribute, out of the wealth of his wisdom, an introductory article on some fundamental principles in the training of the student. His message will be pondered by all thoughtful members of our profession, and should help parents to grasp something of the true purpose and meaning both of medical education and of education in general. We would draw attention also to Professor W. E. DIXON's valuable note on the place of pharmacology in the teaching of medicine, and to the review at page 412, by an authoritative hand, of the important changes now being made in the medical curriculum at large and in the requirements for the public health course.

Apart from these and other special articles, the student will find in subsequent pages an account of the course of education required of him, the places where this training can be obtained, and the universities and other bodies which test the knowledge gained and stamp successful candidates with their several hall-marks. The medical courses of all the universities and corporations in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same for all students. But within these broad lines there are many differences between the requirements of the various teaching and examining bodies. The choice must therefore be made early. To prevent a false step at the outset the student and his advisers should have a clear idea of the object to be aimed at, of the relative value of the degrees and diplomas open to him, and of the comparative difficulties they present.

The conditions with which those wishing to enter the medical profession must comply are regulated by the General Medical Council, which is a statutory body established under the Medical Acts; a statement of its requirements is given at page 414. It will be observed that many changes are about to be made, and this section should be studied with care. The examination of candidates as to their fitness to practise medicine is left to the universities and to certain corporations in England, Scotland, and Ireland. But the Council endeavours to make sure that the tests at each stage do not fall below a certain standard, and that the persons examined have undergone proscribed courses of instruction at a recognized medical school. Successful candidates at such examinations eventually receive from the body holding them either degrees, in the case of the universities, or diplomas or licences, in the case of the corporations, entitling them to claim insertion of their names in the *Medical Register* kept by the General Medical Council. Holders of diplomas and licences once made up the great majority of all medical men, especially in England and Wales. But universities have greatly multiplied, and so many practitioners are now graduates that a student at the threshold of his career will do well to aim at a university degree, though it may be desirable to take also a diploma or licence.

Beyond the qualifications on the strength of which the General Medical Council admits to the *Medical Register* most of the examining bodies bestow on candidates who have passed further tests such higher titles as Doctor of Medicine and Fellow. As a rule these are well worth obtaining, though the difficulty of doing so, and the added professional status they confer, vary. The man who looks forward to a career as a consulting physician should obtain the M.D. degree of a recognized university, and also the membership of one of the three Royal Colleges of Physicians, according to the part of the British Isles in which he means to practise. If he wishes to devote himself to surgery he must in like manner seek the Fellowship of one of the Royal Colleges of Surgeons. There are also diplomas in a growing number of special branches of work, such as public health, tropical medicine, and psychological medicine, which are superfluous for most practitioners, but either useful or indispensable for those who wish to specialize in these subjects.

What, asks the parent, will it cost to make my son a doctor? The answer to this is not easy to give in a single precise statement, because the outlay varies within wide limits. Besides differences in the charges made by medical schools for instruction there are differences in examination fees, as well as in those payable for the certificates of qualification. Again, not all students, however industrious, pass examinations with equal facility. Since in any case professional education must continue for five years at least (a period exceeded by the vast majority), and since the cost of living in different parts of the country varies much, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession must assume that a medical education—first and last—will cost at least £1,500. On the other hand, the number of scholarships now offered is larger than in the past; in the Scottish universities bursaries are numerous, and the Carnegie Trust gives assistance to many Scottish students. It will be seen, however, that, as compared with other professions, the period of training in medicine is long, and for most students costly. There is also to be remembered the time of waiting after qualification when income is apt to lag behind expenditure.

Having obtained a registrable qualification, many paths are open—for example, general practice, Government service at home or abroad, and special work in public health or mental disorder, in scientific research, or in one of the many modern subdivisions of medicine and surgery. Most of these different paths in medicine are considered in detail in the later sections of this Educational Number, where an account will be found also of the facilities for post-graduation teaching in London and other large centres; but a few words may be said here about general practice and the work of a consultant or specialist.

General practice is still the goal of the great majority of all medical students, and it has been well said that this country produces the finest body of general practitioners in the world. The work is hard and none too well paid; yet it appeals to many of the very best students, which is fortunate, both for medicine and for the public. This career is usually entered upon in one of three ways. The newcomer may take a house and wait for patients to seek his services; he may purchase the goodwill of a practice rendered vacant by retirement or death; or—perhaps best of all—he may become a partner in an established practice. Success in the work of a private practitioner demands, however, a great deal of knowledge other than that gained at the medical schools, and consequently a man is more likely to be accepted as a partner, or to succeed on his own account, if he has already some experience of family practice as an assistant or deputy. An all-round knowledge of practical medicine, surgery, and obstetrics should, if possible, be supplemented by skill in some particular branch of practice,

while the value to a general practitioner of having held one or more resident hospital posts is incalculable. As for the man whose aim is to become a consultant or specialist, his path, though full of interest, is seldom smooth. For him success will depend in the long run not only upon mental gifts and capacity for hard work, but, as is true of practitioners of all branches, on the possession of those qualities which inspire confidence both in patients and in colleagues. Moreover, since he cannot expect at first to pay his way as a specialist, he must either have the means to support himself for an uncertain period or be prepared by teaching or in other ways to defray expenses. Anyone who enters our profession with the sole idea of making money has, of course, mistaken his calling. The competent practitioner can always earn a living, but the main reward of the medical life is the knowledge of good work well done. Whatever the branch of practice chosen, few doctors make more than a moderate income, and the earnings of even the most successful compare but ill with those won by men of equal ability in other walks of life.

One effect of the war was a great increase in the numbers of medical students, both men and women, but especially women. This matter has been fully discussed in these pages, but we give here a short summary of the position as it appears to-day. It may be read in conjunction with the note at page 413 on the numbers of the medical profession. In the thirteen years before the war the annual entry of first-year medical students in Great Britain and Ireland averaged 1,400. From 1914 until 1920, although many left to serve with the Forces, the whole number actually studying in the medical schools grew steadily larger; in May, 1916, this total was 6,103; in May, 1918, it was 7,630; and in the following January it had risen to 9,490. Then, during 1919, when demobilization was in active progress, 3,420 new students were registered, being 1,105 greater than the "record" entry of 1891. The number of new students registered in 1920 fell to 2,531, and in 1921 to 1,808. The great increase after the armistice was largely due to the return to their studies of those who had been on naval or military service. As a result many of the schools became overcrowded, and some were obliged to turn away applicants. The recent fall in the entries has therefore been welcomed, both by the overstrained teaching institutions and by those who doubted whether there would be work enough to go round when the present generation of students becomes qualified. After 1914, as has been said, the number of women going in for the study of medicine grew very rapidly, and in consequence the proportion of medical women has increased and is increasing. But their services, it seems, are less in demand than during the war, while the ratio of medical practitioners to population is now greater than at any time in the past half-century. Hence, all the women students now requiring qualification may not find professional work ready to their hand. These are points for parents to consider before encouraging their daughters to embark on the study of medicine.

The prospects held out by the various public medical services are briefly indicated in later sections. Our profession as a whole seems to be passing through a stage of transition, and it is especially difficult to foresee clearly the future of private practice. The fundamental importance of the work done by the general practitioner is better understood, and the Medical Consultative Council of the Ministry of Health agrees with the British Medical Association that an efficient medical service for the community must be based on that. Two years ago there was thought to be some likelihood that the Government would bring in a Medical Service Bill, but a comprehensive measure appears now more remote than ever, and it is improbable that the present Government would wish to set up a whole-time salaried State medical service against the opposition of a large majority of the profession and the public. Nevertheless, the position of the private doctor has changed and is changing. It was profoundly affected by the national insurance scheme, and great roads into the sphere of family practice have been opened by the spread of specialism and the growth of special

services. It is very plain, therefore, that in these times of social and professional change the doctor needs a strong sense of *esprit de corps*. The effect of many modern measures is so far-reaching that no practitioner whatever his work or position, can safely stand aside from his fellows. Medicine is a calling which the general public and public authorities have come to look on as partly a form of philanthropic service; the compliment is deserved, but would be more welcome if it were less often a cloak for inactivity. Furthermore, the aims and requirements of modern medicine are still imperfectly understood by many lay persons. Thus the financial interests of the profession and the objects and methods of medical science are in constant risk of attack from one quarter or another, sometimes openly, sometimes insidiously. It follows, therefore, that medical men and women must band themselves together for the common protection of themselves and their profession. The first step after qualification should be to join the British Medical Association.* The Association was founded in 1832 to promote the progress of medical science and to maintain the honour and interests of the medical profession. Its record of ninety years' work shows that it has well fulfilled these aims, and the strength and vigour of the organization are greater to-day than ever.

A NEW ERA IN MEDICAL EDUCATION.

A FULL account of the resolutions and recommendations of the General Medical Council which apply as from the beginning of 1923 is given in the present issue of the JOURNAL. Here we propose to call attention to some of the salient features of the new scheme, both of study and of examination.

The Revised Curriculum.

The matriculation age is increased from 16 to 17 years. Formerly, the length of the curriculum is not added to; practically it is, by transferring to preliminary study and examination the subjects of elementary physics and chemistry in their purely scientific aspects. In their applications to the professional courses—as in biophysics, biochemistry, and pharmacological chemistry—appropriate instruction is to continue throughout the curriculum, and is to be tested by examination, so that the student shall no longer be able to put behind him as passed and done with the knowledge which he acquired as a preliminary. If he has had no facilities at a secondary school or otherwise for obtaining what is necessary for the preliminary examination in these subjects, then he can come for it to the university or college, but study there will not count for the medical curriculum.

In biology it is understood that comparatively few secondary schools are equipped for elementary tuition; but the Council has suggested an ingenious arrangement for utilizing the work of such schools as are qualified for the purpose. The examination will not be "pre-curriculum," but the instruction may be so, and a licensing body can allow students who so desire to sit for the examination immediately after matriculation. Here again, however, the applications of biology to medicine, surgery, and midwifery will continue throughout the courses.

The Council attaches great importance to the reservation of sufficient time for the later subjects of study, free from all worries about passing the examinations of the earlier parts. To that end it recommends what is practically a block system. A minimum of three years should be available, not merely after the courses of anatomy and physiology have been taken, but after the professional examinations have been passed. The value of this proposal is obvious.

* The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in the United Kingdom. A member who joins within two years of registration as a medical practitioner pays 1½ guinea a year up to the end of the fourth year after registration; members joining after July 1st pay half the subscription for that year. Full particulars can be obtained from the Medical Secretary, 423, Strand, London, W.C.2. A brief note on the objects and constitution of the Association will be found at page 453.

Examination Reform.

Another notable feature is that in assessing marks in the several examinations account may be taken of "duly attested records of the work done by the candidate throughout his course of study" in the subject. This is an effort to meet the long felt difficulty that a man's mental agility, or the want of it, counts far too much in his being passed or rejected. The difficulty is real, but the remedy is not easy, and the Council is wise in the cautious approach it made towards a solution. Where, as in the colleges, a student will only by chance come before his own teacher as an examiner, absolute impartiality in the attested records will be necessary. A teacher must not play for popularity with students by too easy certification of diligence. On the other hand, at the universities, where the teacher is always one of the examiners, no personal like or dislike of a student must influence the report of the internal to the external examiner. The scheme will indeed put a serious ethical obligation on all concerned, and the Council will doubtless watch its operation with keen and critical interest. This leads to the remark that the teaching of medical ethics is now an acknowledged part of the curriculum.

Besides the Resolutions of the Council in regard to professional education and examination (see pp. 414-416), a series of additional Resolutions were adopted on May 26th, 1922, as follows:

(a) That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of Medicine;

(b) That each Licensing Body should make adequate arrangements for the effective correlation of the several subjects of study throughout its curriculum;

(c) That the teaching of Anatomy and Physiology should include as a regular part of the courses the demonstration on the living human body of structure and function;

(d) That the curriculum should be so arranged that a minimum period of three years shall in every case be available for study after the completion by the student of the Professional Examinations in Anatomy and Physiology held at the close of the second year;

(e) That the curriculum should be so framed as to afford sufficient opportunities for the study, during the last three years of the course, of Physics, Chemistry, Biology, Anatomy, and Physiology in their practical applications to Medicine, Surgery, and Midwifery, and that the student's knowledge of these applications should be subject to test in the Final Examination;

(f) That before the student is admitted to his clinical appointments he should have received practical instruction in clinical methods and in the recognition and interpretation of physical signs;

(g) That instruction should be given, in the courses of Forensic Medicine and Public Health or otherwise, on the duties which devolve upon Practitioners in their relation to the State, and on the generally recognized rules of Medical Ethics. Attention should be called to all Notices on these subjects issued by the General Medical Council.

Training in Preventive Medicine.

The first of these resolutions is that "throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine." This should be borne in mind by every teacher throughout the whole curriculum, and not merely in the clinical subjects. As indicated in a questionnaire issued by the Council in 1918, all the earlier subjects—Physics, Chemistry, Biology, Physiology, Anatomy, and very obviously, Pathology, Bacteriology, and Therapeutics—afford opportunities from the very beginning for instilling into the mind of the student the necessity for his constantly keeping in view, in all the advice and treatment he may give throughout his life, the primary importance of promoting the general health of those who entrust themselves to his care, and of preventing trivial ailments from developing into definite disease. In his presidential address in November, 1918, Sir Donald MacAlister pointed out that if "the efficient practice of their profession" by doctors was "to be judged by new civic standards, and to be carried on under new conditions," the student would have to be trained accordingly. The era of that training begins formally in 1923. Though no details are given in the resolution already quoted, and though it may

require some change of orientation by any teachers who may have hitherto given no special heed to the bearings of their subject on the maintenance of health and prevention of disease, yet it is not to be doubted that they will now join heartily in what will indeed be an epoch-making advance in medical education in this country. Its reflex and reward will surely be found as time passes in a diminution of sickness and prolongation of life, in the raising of the present standards of physical health and national welfare.

New Rules for the D.P.H.

It is important to note the bearing of this development of the teaching of disease prevention to all students of medicine on the stringent rules which will come into force at the beginning of 1924 for the obtaining of diplomas in public health. Fears have been expressed that the stiffening of the requirements will discourage those who intend to go into ordinary medical practice from taking the additional qualification which would specially fit them for co-operation with the health officer of their district. The reply is twofold: From now onwards all new practitioners will have received tuition which will qualify them generally for such co-operation, and in addition they are already being systematically educated in "the duties which devolve upon practitioners in their relationship to the State." The balance, therefore, seems clearly on the right side as to the ordinary practitioner, and it is unquestionable that there will be advantages in strengthening the education of those who aspire to a life spent in the public health service. In America, it may be mentioned, the standard of study for the "doctorate" of public health will at most medical schools probably correspond with that for the new health diploma in this country.

THE NUMBERS OF THE MEDICAL PROFESSION.

A REVIEW OF FORTY-FIVE YEARS.

SINCE 1876 the General Medical Council has kept an analytical record of the number of persons whose names were entered in, added to, or removed from the *Medical Register* in each year. The *Medical Register* has been in existence since the Council was constituted under the provisions of the first Medical Act of 1858; but up to 1876 no such data as those were ascertained or preserved.

The figures for each year since 1897—showing (a) the number of names added by registration in each part of the United Kingdom, (b) those added to the colonial and foreign lists, (c) the number of names restored, and (d) an analysis of those removed—are given in a statistical table published in the current *Medical Register*. The corresponding figures for the earlier years are to be found in copies of the *Register* published previous to 1898.

In order to gain a general view of the numerical strength of the medical profession during the past forty-five years (the period for which these figures are available), we have extracted from the tables and set down in parallel columns the total number of names in the *Medical Register* on December 31st of each year since 1875, and the total number added annually by registration between 1876 and 1921:

Numerical State of the "Medical Register."

Year.	Names added in Year.	Total No. on Dec. 31.	Year.	Names added in Year.	Total No. on Dec. 31.
1875	—	22,200	1899	1,251	35,836
1876	1,009	22,713	1900	1,345	36,355
1877	940	22,841	1901	1,318	36,912
1878	996	22,600	1902	1,275	37,232
1879	996	22,516	1903	1,233	37,878
1880	1,123	22,936	1904	1,168	38,492
1881	1,053	23,275	1905	1,240	39,060
1882	1,171	23,801	1906	1,197	39,429
1883	1,304	24,517	1907	1,221	39,827
1884	1,388	25,321	1908	1,137	40,257
1885	1,377	25,993	1909	1,143	39,818
1886	1,431	26,452	1910	1,062	40,483
1887	1,531	27,246	1911	1,042	40,913
1888	1,184	27,939	1912	1,157	41,439
1889	1,305	28,348	1913	1,168	41,940
1890	1,266	29,163	1914	1,433	42,378
1891	1,345	29,555	1915	1,526	43,225
1892	1,513	30,590	1916	1,202	43,481
1893	1,579	31,444	1917	1,134	43,819
1894	1,426	32,637	1918	1,077	43,926
1895	1,446	33,601	1919	1,322	44,510
1896	1,385	34,478	1920	1,457	44,761
1897	1,230	34,642	1921	1,760	45,493
1898	1,210	35,057			

In order to gauge the varying proportion of registered medical practitioners to population during the period under review we put down the total population of the United Kingdom at each decennial census and the corresponding figure showing the total number of names on the *Medical Register*:

Year.	Registered Practitioners.	U.K. Population.
1871	31,845,379
1881	23,275	35,241,482
1891	29,555	38,104,975
1901	35,912	41,976,827
1911	40,913	45,370,530
1921	45,408	46,000,000*

* Conjectural; probably an under-estimate. The census of 1921 was taken only in Great Britain.

It will be seen from these parallel columns of figures that no general tendency during the past forty-five years has been towards an increase in the ratio of doctors to population. The number of registered practitioners at the end of last year is almost exactly double the number at the end of 1876, but the population within that period only increased by about 1 per cent.

THE GENERAL MEDICAL COUNCIL.

The General Medical Council was set up by the first Medical Act of 1858, and consists of thirty-eight members, six of whom are elected by the medical profession, five nominated by the Privy Council, and the remainder are representatives of the universities and such medical corporations of the United Kingdom as have a statutory right to issue diplomas. Under the Dentists Act, 1921, three additional members have been appointed by the Privy Council for dental business; they must be registered dentists and members of the Dental Board. Its headquarters are at 44, Hallam Street, Portland Place, W.1, and it has branch offices at 20, Queen Street, Edinburgh, and 35, Dawson Street, Dublin. Its duties are to control the medical and dental professions in the interests of the general public, and to that end to maintain a register of legally qualified practitioners. It is admission to this register, and not the possession of a degree or diploma, that constitutes a person a legally qualified practitioner. The Council is bound to admit to the Register those who hold the qualifications granted by the bodies represented among its members, but it exercises supervision through the Privy Council over the terms on which those bodies grant such diplomas or degrees, and it can erase from the *Medical Register* or the *Dentists Register* the name of any medical man or dentist who has been convicted before a court of law of an ordinary crime or of a serious offence against public order, or who is proved before the Council itself to have been guilty of certain actions which the Council regards as professionally "infamous." Its disciplinary powers are limited to legally qualified practitioners, and it has no control whatever over irregular practitioners of any kind. In that respect it differs from the Midwives Board in England and Scotland, which can penalize unqualified midwives, even though they make no pretence to be on the register, and the Dental Board of the United Kingdom, which, when the Dentists Act, 1921, is enforced, can prosecute unregistered persons practising dentistry.

An account of the Recommendations that the Council has given up in respect of the education of medical students is as follows.

REGISTRATION OF MEDICAL STUDENTS.

The Council recommends that every intending student of medicine should be registered as such at one of its three offices.

On or after January 1st, 1923, candidates will have to produce evidence (a) that they have attained the age of twenty years; (b) that they have passed an examination in general education which is accepted for matriculation in a university in the United Kingdom, or the Responsions or the Previous Examination*; (c) and in addition thereto that they have passed an examination in chemistry and physics conducted or recognized by one of the licensing bodies.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be

obtained from one of the offices of the General Medical Council itself or from one of the various licensing bodies and medical schools.

The regulations with regard to registration apply equally to medical and dental students, with the exception that in the case of the latter pupilage with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

PROFESSIONAL EDUCATION.

The rule is that it is only from the date which appears against his name in the *Students Register* that the medical student's career officially begins; thereafter five years must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts, but to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona fide study, and in every course the following subjects should be included:

- (i) Elements of General Biology, including an introduction to Embryology. This course, if the Licensing Bodies permit, may be taken before registration, and the examination may be passed immediately after registration.
- (ii) Chemistry, Physics, and Biology in their application to Medicine.
- (iii) Human Anatomy and Physiology, including Histology, Elements of Embryology, Biochemistry, and Biophysics.
- (iv) Elementary Bacteriology, prior to regular clinical appointments.
- (v) Pathology, general, special, and clinical, and Morbid Anatomy.
- (vi) Pharmacology and Materia Medica, to be taken concurrently with clinical instruction.
- (vii) Forensic Medicine, Hygiene, and Public Health.
- (viii) Medicine, Clinical Pathology, Acute Infectious Diseases, Tuberculosis, Mental Diseases, Skin Diseases, and Vaccination.
- (ix) Surgery, including applied Anatomy and Physiology and Clinical Pathology; Anaesthetics, Diseases of the Eye, Ear, Throat and Nose, Radiology, Venereal Diseases, and Orthopaedics.
- (x) Midwifery and Diseases of Women, including ante-natal conditions and infant hygiene.

The Council recommends that in the last three of the five academic years clinical subjects shall be studied.

The first two years must be passed at a school of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body.

SPECIAL CONSIDERATIONS.

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order:

- (1) Pass an examination in arts;
- (2) Pass an examination conducted, or recognized by a licensing body in elementary physics and elementary chemistry.
- (3) Enter himself at a medical school or other scientific institution approved by the Council;
- (4) Get himself registered as a medical student;
- (5) Study for a minimum of five years certain prescribed subjects;
- (6) Meanwhile pass sundry intermediate examinations; and at the end of the fifth year pass a "qualifying examination" which will entitle him to receive from a licensing body a legal authority to practise.

The Minimum Period.—It must be remembered that the period of five years is a minimum; more is often required even by the man of good abilities and reasonable industry. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Thus, for instance, before presenting himself for any examination he must be "signed up" for the subjects covered by that examination; this means that his teachers have to certify

that he has diligently attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place he may miss enough of them to make it impossible for him to be signed up. Then again, should he fail to satisfy the examiners at some examination, he cannot present himself for re-examination for at least three months. This generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by the need for restudying the subjects in which he has failed, the Examining Boards usually insist upon a definite interval elapsing between one examination and the next. Further, many Boards have refused to recognize lectures and classes which have been attended before the student has passed the requisite examination in earlier subjects, and the Council now recommends that the professional examinations in anatomy and physiology be passed before the minimum period of three years' subsequent study be entered on. In other words, no clinical study should count as such until these examinations have been successfully completed. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the beginning of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a fact, the majority of students take longer.

In speaking of the minimum period, it is to be remembered also that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or the diplomas of the Royal Colleges. Those who wish to take a higher qualification—for instance, the F.R.C.S. Eng.—must prolong their work for another year or more. So, too, must in some cases those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended when he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

MEMORANDUM ON STUDENTS' REGISTRATION.

The following memorandum has been drawn up by the Registrar of the General Medical Council as to the procedure for those who desire to be registered as medical or dental students.

The requirements for the registration of medical and dental students are the same, and every intending student should, in his own interest, register as soon as he commences his professional curriculum.

A recognized examination in general education must first be passed. If the student intends to obtain a university degree, he should apply to the university he selects for information as to its matriculation requirements in arts or pure science, or as to any examinations which may be accepted in lieu of its matriculation examination. If the student intends to obtain a qualification from one of the licensing corporations (these are the Conjoint Boards in England, Scotland, and Ireland, the Society of Apothecaries of London, and the Apothecaries' Hall of Dublin), any of the examinations in Appendix A will be accepted. The subjects required are (1) English, (2) Mathematics (elementary), (3) a language other than English, and (4) an additional subject or subjects, as required by the regulations of the body chosen from the following—namely, Natural Science, Latin, Physical Science, or other language accepted by the body chosen.

The requirements of _____ in general education being satisfied, it is then necessary to pass an examination in Elementary Chemistry and Elementary Physics, which is conducted or recognized by one of the licensing bodies, that is, university or corporation. The student should write to the body whose qualification he desires to obtain (a list will be found in Appendix B) for information in regard to its requirements for this examination.

These two examinations having been passed, and the student having attained the age of 17 years, he should apply to one of the universities in Appendix B or one of the medical schools in Appendix C for admission in order to commence therein his professional curriculum. Immediately his course of medical study has been begun, he should apply to the Dean of the school, or to the Registrar of one of the branches of the General Medical Council, for a form of application for registration as a student, and should have it completed and sent in to one of the Branch Councils as soon as possible. There is no fee for this registration. The medical curriculum will extend for at least five years, and the dental curriculum for at least four years, from the date of registration as a student.

A student who has studied the subject of elementary biology at an institution recognized by one of the licensing bodies may, if the

body sees fit, be admitted to the professional examination in the subject immediately after his registration as a student. In the information in regard to this, he should apply to the body which has the medical qualification he seeks.

A Dental Student may commence his curriculum, if he so desire as a pupil with a registered dental practitioner; but it is desirable if possible, that he should commence professional study at a dental school. If, however, he is apprenticed to a dental practitioner, may have to take out a course of four years of mechanical dentistry, and this will have the effect of lengthening the duration of his curriculum to five or six years instead of four.

The addresses of the Branch Registrars are:

General Medical Council, 44, Hallam Street, Portland Place
London, W.1.

Scottish Branch Council, 20, Queen Street, Edinburgh.
Irish Branch Council, 35, Dawson Street, Dublin.

PROFESSIONAL EXAMINATION.

The Council's Recommendations.

The following Recommendations of the General Medical Council in regard to professional examinations for medical and surgical qualifications were adopted on May 27th and 29th, 1922:

1. In order to secure due continuity and sequence in medical study, two or more Professional Examinations in the earlier subjects should be held antecedently to the Final Examination in Medicine, Surgery, and Midwifery.
2. Three years at least should intervene between the date of passing the Professional Examination in Anatomy and Physiology and that of admission to the Final Examination in Medicine, Surgery, and Midwifery.
3. A candidate remitted in any subject of a Professional Examination should, before he is readmitted to examination therein, be required to produce satisfactory evidence that he has, during the interval of remission, pursued the study of the subject in which he was rejected. Candidates who obtain less than 30 per cent. of the marks in any subject should be remitted for a longer period than three months.
4. In all the Professional Examinations sufficient time should be work, in order to test the thoroughness of the and to encourage practical methods of study. their examination work should be carefully supervised.
5. Two examiners should always participate in the oral examination of a candidate, except in subordinate parts of practical examinations.
6. In all written examinations the questions in each subject should be submitted for the approval of all the examiners in that subject.
7. In all written examinations an average of at least half an hour should be allowed for a candidate to answer each question.
8. It is desirable that examiners, and in particular those for the Final Examination in Medicine, Surgery, and Midwifery, should be appointed or re-elected for at least three consecutive years.
9. Whatever may be the system of marking, the percentage for a pass in each subject should be not less than 50.
10. In the regulations for the several examinations it should be provided that examiners, in assessing marks, be empowered to take into account the duly attested records of the work done by the candidate throughout his course of study in the subject of the examination.
11. The Final Examination in Medicine, Surgery, and Midwifery, with the exception of the Clinical and Practical Examination in Midwifery and Gynaecology, must not be passed before the close of the fifth academic year of medical study.
12. The three portions of the Final Examination in Medicine, Surgery, and Midwifery should not be further subdivided into sections which may be entered for or passed separately.
13. Compensation in respect of marks as between the three different portions of the Final or Qualifying Examination—namely, Medicine, Surgery, and Midwifery—is contrary to the intention of the Medical Act (1886).
14. The Final Examination should include clinical and practical examinations in Midwifery and Gynaecology.
15. The clinical examination in Medicine, Surgery, and Midwifery should be held in properly equipped hospitals or examination halls well provided with suitable patients.
16. In the examinations in clinical medicine at least one hour, and in clinical surgery at least half an hour, should be allowed to the candidate for the examination of, and report on, his principal case.
17. In Medicine, in Surgery, and in Midwifery, no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to the whole examination; or who fails to obtain 50 per cent. of the marks assigned to the clinical examination; or who fails to obtain 40 per cent. of the aggregate of the marks assigned to the written and oral examinations.
18. In Midwifery, where a clinical examination is not held, the duly attested records of the work done by the candidate in clinical midwifery must be presented to the examiners for assessment in the Final Examination; and no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to Clinical and Practical Midwifery and Gynaecology.
19. The Final Examination should include the examination of secretions, the testing of urine, clinical microscopy, and prescription writing; and there should always be an oral examination in Medicine, Surgery, and Midwifery, which should include an examination on pathological specimens.
20. At the Final Examination each candidate should be submitted to a practical and oral examination in Pathology (macroscopic and microscopic), unless this has been included in a Professional Examination preceding the Final Examination.
21. Whatever be the method of entry for the Final Examination all candidates should be required to complete the three portions of the Final Examination within a period of nineteen months.

The English Universities.

THERE are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties. Until recently the only exception was the University of Wales, whose constituent colleges are those of Aberystwyth, Bangor, Cardiff, and Swansea. This university grants degrees, and has laid down a six years' curriculum for candidates for the M.B. and B.Ch. degrees, and it now provides, at the Welsh National School of Medicine at Cardiff (see p. 421), instruction in all the subjects of the medical curriculum.

UNIVERSITY OF OXFORD.

The professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a diploma in Public Health and a diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in Arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period, for some of the subjects chosen for the final stage of the arts course may be the same as those in which examinations would in any case have to be passed for the medical degrees.

In accordance with a statute which came into force on October 7th, 1920, women may be matriculated and admitted to degrees in the university. The statute is retrospective under certain conditions. Before matriculation a woman must have been admitted as a member of one of the five societies of women students (Lady Margaret Hall, Somerville College, St. Hugh's College, St. Hilda's Hall, or the Society of Oxford Home Students). Women members of the university are admitted to all degrees, except those in Divinity, under the same conditions as those laid down for men in regard to examinations, courses of study, and fees, and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology, ophthalmology, and public health.

A candidate may obtain the B.A. degree in either of the following ways, of which the latter constitutes the normal course for medical students:

(a) By passing Responsions (or one of the examinations which are accepted as equivalent to the Scriptura examination, or in the event of a candidate failing to pass the examination on some subject, in three subjects, two of which may be preliminary examinations in natural science.)

(b) By passing Responsions, the Scripture examination, some of the preliminary examinations in the Natural Science School, or the Honour School of Mathematics in the first public examination; and one of the final honour examinations. The Final Honour School of Natural Science (Physiology) is that usually taken.

Responsions and the preliminary examinations in Natural Science may be passed before a candidate is a member of the university; Moderations and Scripture can be passed in or after the second term; the final pass school may be taken any time after Moderations; a final honour school may be taken at the end of the third or fourth academical year—that is, within nine or twelve terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions have been passed.

PROFESSIONAL DEGREES.

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First B.M. and the Second B.M. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every

¹ The four subjects of the medical preliminary examinations are four of the subjects of the natural science preliminary, and can be commenced

is matriculation and by becoming either a non-collegiate student.

candidate at the First B.M. is examined in human anatomy, in physiology, and in organic chemistry, but is excused from physiology if he has obtained a first or second class in the Honour School of Physiology, and from organic chemistry if he has satisfied the Examiners in Part I of the Honour School of Chemistry. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine, and hygiene, materia medica, and pharmacology (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the eighteenth term from the day of his matriculation, and not until a period of at least twenty-two months have elapsed from the date of his passing the first examination, and he must take all the three subjects at one and the same time.

Before admission to the Second B.M. examination the student must produce certificates of instruction from a medical school recognized by the university of having acted as clinical clerk and dresser, each for six months, and as *post-mortem* clerk for three months, of attendance on labours, of instruction in infectious and mental diseases and ophthalmology, and of proficiency in vaccination and the administration of anaesthetics. He must also produce certificates of attendance in laboratory courses in pathology, bacteriology, and pharmacology, either in Oxford or in a recognized medical school.

D.M. AND M.Ch. DEGREES.

A Bachelor of Medicine who wishes to proceed to the D.M. must have entered his thirtieth term and must present a dissertation for approval by the appointed examiners on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M.Ch. he must have entered his twenty-first term and must pass an examination, which is held in June.

Examinations for the Diploma in Public Health are held in Trinity and Michaelmas terms; that for the Diploma in Ophthalmology is held annually, commencing on the third Monday in July. For the Diploma of Ophthalmology attendance on a course of instruction in Oxford lasting two months is obligatory. Candidates must have their names on the *Medical Register* of the United Kingdom, unless, being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

TEACHING.

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First B.M., and in part those of the Final Examination.

SCHOLARSHIPS.

Most colleges grant scholarships open to intending medical students of £80 a year, tenable for four years, in natural science, chemistry, physics, and biology. Exhibitions of varying value are also awarded in these subjects. At two colleges (University and Pembroke) there are medical entrance scholarships of £100 a year. Particulars can be obtained on application to the college tutors. Scholarships for women are also offered by the various women's colleges, from the principals of whom details of the examinations may be obtained. A Radcliffe Travelling Fellowship of £300 a year, tenable for two years, is conferred annually; candidates must have taken the B.M. degree. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolleston Memorial Prize and the Radcliffe Prize (£50), for research in natural science (including pathology), and the three Theodore Williams Scholarships in Anatomy, Physiology, and Pathology, of the value of £50 each, tenable for two years. A Radcliffe Scholarship in Pharmacology of £50 for one year, open to the University, is awarded annually by the Master and Fellows of University College. A Barney Yeo King's College Hospital Scholarship of £80 is awarded annually.

FEES.

An annual fee of £4 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are: the B.A., £7 10s.; the B.M. and B.Ch., £14; the D.M., £25; the M.Ch., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from

£21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £180, or for women not less than £140.

For further information application may be made to Dr. E. W. Ainsley Walker, Dean of the School of Medicine, University of Oxford.

UNIVERSITY OF CAMBRIDGE.

THE professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Ch.), each of which entitles the possessor to admission to the *Register* by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants diplomas in Tropical Medicine, in Public Health, in Hygiene, in Psychological Medicine, and in Medical Radiology and Electrolgy to medical practitioners, not necessarily graduates of the university. Information regarding these diplomas will be found in later sections under the headings Tropical Medicine, Psychological Medicine, and Public Health. A candidate for the M.B., B.Ch. degrees need not possess a degree in arts; it is sufficient if he has passed the previous examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B.A. degree, preferably by obtaining honours in the Natural Sciences Tripos at the end of their third year.

New regulations are being drafted for Medical and Surgical degrees, to come into force in October, 1923.

PROFESSIONAL EXAMINATIONS.

To obtain the M.B. degree the candidate must pass three examinations, of which the latter two take place twice a year, in the Michaelmas and Easter terms; those who are finally successful may receive the B.Ch. degree (which is a complete registrable qualification) without further examination.

First M.B., or Preliminary Examination in Science.—This comprises (1) chemistry, (2) physics, (3) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the previous examination, paid the matriculation fee, and entered on his first or some later term of residence. During the continuance of the war students could be admitted to this examination though they had not commenced residence. The examination is held three times a year—in October, December, and June.

Second M.B.—This examination, which cannot be passed until the first examination has been completed, comprises Part I, human anatomy and physiology; Part II, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No one may enter Part II unless he has passed Part I. The candidate must be signed up in both subjects and have dissected for six months. The examination for Part I is held in December and June; that for Part II in October and April.

Third M.B.—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with surgery and midwifery, must have completed five years of medical study and be signed up in these subjects and have completed two years of hospital practice. Before admission to the second part the candidate must have completed five years of medical study and be duly signed up in all subjects and have completed three years of hospital practice. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination is in the principles and practice of physic, pathology, and pharmacology.

Act for the M.B.—Before receiving his M.B. degree a candidate who has been successful at the final M.B. examinations has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physic. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence, the candidate sending to the Regius Professor of Physic a thesis, which is laid before the Board.

THE HIGHER DEGREES.

The M.D. degree may be taken by a bachelor of medicine of three years' standing after writing a thesis approved by

the M.D. Degree Committee and keeping a further Act. Previously to the thesis being read a topic taken from the general subject of his thesis (whether it be physiology, pathology, pharmacology, practice of medicine, State medicine, or the history of medicine) is submitted to the candidate, on which he is required to write an extempore essay.

The M.Ch. degree may be granted to a candidate who has qualified for the B.Ch. at least three years previously; he is then examined in pathology, surgery, surgical anatomy, and surgical operations, or submits books or writings of his own which constitute original and meritorious contributions to the science and art of surgery.

FEES.

In addition to college fees, tutorial fees, and the expenses of living, the following examination fees are payable: First M.B., £4 4s.; Second M.B., £4 4s.; Third M.B., £10 10s. For schedules referring to the schools recognized by the University, application should be made to the University.

UNIVERSITY OF LONDON.

Under the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in two branches, and Doctor of Medicine in six different branches. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should secure and carefully study the booklets relating to it.

In no circumstances is a degree granted to anyone, in less than three years after the date at which he passed the Matriculation Examination or obtained registration in some other way; and, unless they are already registered medical practitioners of a certain age and standing, all students must pass not less than five and a half years in professional study subsequent to matriculation.

PROFESSIONAL EXAMINATIONS.

M.B., B.S.—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination, Part I, cannot be passed within six months of the passing of the First Examination. It covers organic and applied chemistry, the candidate's knowledge being tested as in the earlier examination. It is a pass examination, but a mark of distinction may be won. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may sit for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M.B., B.S. Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including therapeutics and mental diseases), pathology, forensic medicine and hygiene, surgery, and midwifery and diseases of women. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and midwifery and diseases of women. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

THE HIGHER DEGREES.

M.D.—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S. unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) Medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and

diseases of women, (5) State medicine, (6) tropical medicine, and, if he wishes, may pass also in another branch at subsequent examination.

The period that must elapse between acquiring the M.E. and sitting for the M.D. in any branch varies between one and two years, according to the nature of the candidate's previous work, and in all cases evidence must be afforded of special study of the subject chosen; both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

M.S.—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are only two branches in which it may be obtained—General Surgery and Dental Surgery.

FEES.

The examination fees have been raised from pounds to guineas for all examinations held after September 1st, 1918. For Matriculation: 2 guineas for each entry. First Examination: 5 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination, Part I: 2 guineas for the first and each subsequent entry. Second Examination, Part II: 3 guineas for each entry to the whole examination. For re-examination in one subject the fee is 4 guineas. M.B., B.S. Examination: 10 guineas for each entry to the whole examination, and 5 guineas for examination or re-examination in either group. M.D. and M.S. Examinations: 20 guineas, and 10 guineas on re-examination. Inquiries should be addressed to the Registrar, the University of London, South Kensington, S.W.7.

UNIVERSITY OF BIRMINGHAM.

This university confers the ordinary medical and surgical degrees—M.B., Ch.B., M.D., and Ch.M.—and also diplomas and degrees in State medicine and dentistry. It has a plan, too, by which, extending his study to six instead of five years, the M.B., Ch.B. candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M.B. those who have passed elsewhere an examination considered to be its equivalent. A degree of Ph.D. is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university.

Students entering the Medical Faculty for the M.B., Ch.B. degrees must have passed either (a) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham; (b) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination, although these subjects are no longer compulsory. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315, Oxford Road, Manchester.

PROFESSIONAL EXAMINATIONS.

The candidate for the M.B., Ch.B. degrees has five examinations to pass. In the second and final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M.B. deals with chemistry, physics, and elementary biology; it may be passed before the student commences residence at the university, provided the regulations as to matriculation have been met. The Second M.B. deals with anatomy and physiology, and the student must pass in both simultaneously. The Third M.B. deals with general pathology and bacteriology, materia medica, and practical pharmacy. The Fourth M.B. takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, therapeutics, and special pathology.

Final M.B.—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must

be prepared with a certificate of having acted as a post-mortem clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, and ophthalmology. In respect to the latter he must show that he has learnt refraction work. He also has to present to the examiners reports by himself on six gynaecological cases, and certificates drawn up by himself regarding four actual cases of lunacy and notes on two others.

M.D.—An ordinary candidate for this degree must be a M.B., Ch.B., of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as holders of the Birmingham M.B., Ch.B.

FEES.

The fee for matriculation is £2, and £2 10s. for each of the first four professional examinations: M.B., Ch.B. degree fee, £10; M.D. and Ch.M. examinations, £12 10s. each. For further particulars application should be made to the Dean of the Medical Faculty, University of Birmingham.

UNIVERSITY OF BRISTOL.

The university grants the following degrees: In medicine and surgery, M.B. and Ch.B., M.D., Ch.M. (the M.D. may be taken in State medicine); in dental surgery, B.D.S., M.D.S. Diplomas in public health (D.P.H.) and dental surgery (L.D.S.) are also granted. Candidates for degrees must qualify for matriculation in the university by passing either one of the school certificate examinations held twice a year in July and in September by the university itself, or the *Higher School Certificate*, or any one out of a list of similar examinations which will be found in the university regulations for matriculation. Candidates over the age of 23 may, under certain circumstances, be permitted to matriculate without examination. The winter session opens on September 29th, 1922.

Candidates who possess a *Higher School Certificate* approved by the Board of Education in physics, chemistry, and biology may count the first year of the curriculum and the first examination—the curriculum being thus reduced to four and a-half years in the university.

PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are three examinations for these degrees. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The first M.B. comprises chemistry, physics, botany, and zoology. The second M.B. comprises anatomy (Part I), and anatomy (Part II). The two groups may be taken separately or together. At the option of the candidate, forensic medicine and toxicology may be taken either with Group I or Group II. First or second class honours may be obtained by a candidate whose work is deemed of sufficient merit, but cannot be awarded to one who has recorded against him a failure at any examination after the first M.B.

M.D.—A candidate must be a M.B. and Ch.B. of at least two years' standing. He has a choice between presenting an original dissertation, undergoing a general examination in medicine (including medical anatomy, medical pathology and bacteriology, systematic and clinical medicine), or passing an examination in State medicine.

Ch.M.—A candidate must have attended, since becoming M.B., Ch.B., and for not less than two years, a public institution affording opportunities for the study of practical surgery, and produce certificates to that effect; the candidate shall be required to pass a general examination in surgery (including

surgical anatomy, surgical pathology and bacteriology, operative and clinical surgery), and to present a dissertation in some department of surgery. He must be of two years' standing as a M.B., Ch.B. The degree is also awarded after examination in general surgery and in special subjects—for example, oto-rhino-laryngology, ophthalmology, and gynaecology.

Applications for other information should be addressed to the Dean of the Medical Faculty.

DENTAL DEPARTMENT.

The university grants the degrees of Bachelor and Master in Dental Surgery (B.D.S., M.D.S.) and a Diploma in Dental Surgery entitling to the letters L.D.S. The courses of the university are available equally for these qualifications and for those of other licensing bodies. Both courses are open to men and women alike.

Fees.—For the entire curriculum, including the mechanical laboratory, lectures, laboratory work, and hospital practice, if paid in one sum: For the B.D.S., 215 guineas; for the L.D.S., 180 guineas. Fee for the mechanical laboratory if taken alone, 20 guineas per annum. Further details may be found in the prospectus.

UNIVERSITY OF DURHAM.

To its own graduates, who may be of either sex; this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M.B., B.S.), and Doctor of Medicine (M.D.), and Master of Surgery and Doctor of Surgery (M.S. and D.Ch.); it also grants special degrees and diplomas in Public Health, Psychiatry, and Dental Surgery. To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts, or even to commence that period by matriculation. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, Newcastle-on-Tyne, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere, but not less than a year must elapse between the date when the student satisfies the requirements of the university as regards matriculation and his presenting himself for the Final M.B., B.S. Examination.

The university has its own matriculation examination, but accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations for the M.B., B.S. degrees. Each is held twice a year—in March and June. The first deals with elementary anatomy and biology, chemistry, and physics; the second with anatomy and physiology; the third with pathology, elementary bacteriology, medical jurisprudence, public health, materia medica, and pharmacy. At the final M.B., B.S. the candidate is examined in medicine and clinical and psychological medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical gynaecology; therapeutics; diseases of the throat, nose, and ear; diseases of the skin; and diseases of the eye.

M.D.—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine for 1921-22. If the candidate is not a M.B. of the university, he must be a practitioner of fifteen years' standing, 40 years of age, and submit to special tests.

M.S.—Candidates for this degree must have been engaged in practice for at least two years subsequent to becoming M.B., B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

FEES.

The following fees are payable: Matriculation or its equivalent, £2; First, Second, and Third M.B., B.S. Examinations, each £5; Final M.B., B.S., £10; M.D. and M.S., £5 for each examination and £6 6s. for the degrees of M.B. and B.S. The fee for the degree of M.D. is £10.

Further information may be obtained from Professor Howden, Registrar, University of Durham College of Medicine, Newcastle-on-Tyne.

UNIVERSITY OF LEEDS.

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, in psychology, and in dental surgery.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years; two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in (1) English composition and literature; (2) English history; (3) mathematics; (4) three of the following, one of which must be a language: (a) Latin, (b) Greek, (c) French, (d) German, (e) some other modern language approved by the Board, (f) either mechanics or physics, (g) chemistry, (h) geography, (i) natural history or botany, (j) general experimental science. Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., Ch.B. number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation and a period of approved work in the respective subjects.

Second M.B.—This examination may be taken in two parts: (a) anatomy and physiology, including practical work; (b) materia medica and pharmacy, including actual compounding of drugs. The candidate's certificates must show, among other things, that he has dissected during at least five terms.

Final M.B.—This may be divided into three parts. The first (pathology and bacteriology) may be taken at the end of the tenth term; the second (forensic medicine and public health) and the third (medicine, surgery, obstetrics, and pharmacology and therapeutics) cannot be taken before the end of the fifth year; before admission to the examination in its subjects the candidate, besides ordinary certificates, must produce proof that he has done both intern and extern maternity work, and received clinical instruction in gynaecology, in diseases of the eye, skin, or larynx, and in the administration of anaesthetics. This division covers all branches of surgery, medicine (including mental diseases and diseases of children), and obstetrics and gynaecology. First and second class honours may be obtained in this division.

M.D.—A candidate for this degree must be a M.B., Ch.B. of the university of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved, he may be required to write a short extempore essay on some topic connected with medicine, and may be examined orally on the dissertation or other work submitted.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on ophthalmology and one on bacteriology; he is then examined on the subject of surgery in all its branches.

FEES.

The matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £5 (£7 for Ch.M.); and £3 on readmission. On conferment of the degree of Ch.M. £7 is payable, and £6 for the M.D. degree.

UNIVERSITY OF LIVERPOOL.

This university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B., M.Ch.Orth., and Ch.M.), gives degrees in dental surgery (B.D.S. and M.D.S.), a degree in hygiene (M.H.), and degrees in veterinary science (B.V.Sc., M.V.Sc., and D.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), public health (D.P.H.), veterinary hygiene (D.V.H.), and medical radiology and electrolgy (D.M.R.E.).

MATRICULATION.

The Matriculation Examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, which accepts under certain conditions the test of several other bodies as its equivalent. The Faculty of Medicine has power to exempt from examination in corresponding subjects in the first M.B. examination any student who has obtained a certificate at a Higher School Certificate examination in the group including chemistry and physics, and who has reached a standard deemed satisfactory in the subject of exemption. Of the five years' curriculum, not less than two must be passed in the university itself, one such year being subsequent to the date of passing the first M.B. Examination.

PROFESSIONAL EXAMINATIONS.

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, inorganic, organic, and physical; (2) biology, including zoology and botany; (3) physics. Section 2 may be taken alone or in conjunction with Sections 1 and 3.

Second M.B.—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology; and (b) (3) materia medica and pharmacy, (4) pharmacology. Candidates may present themselves in (a) and (b) separately.

Final M.B.—The subjects of the Final Examination are: (1) General pathology, morbid anatomy, and bacteriology; (2) forensic medicine, toxicology, and public health; (3) obstetrics and diseases of women; (4) surgery, systematic, clinical, operative, and practical, including ophthalmology; (5) medicine, systematic and clinical, including mental diseases and diseases of children and therapeutics. The examination is divided into three parts: Part I, subject 1; Part II, subject 2; Part III, subjects 3, 4, and 5. Candidates may present themselves for examination in the three parts at the same time, or in any two parts together, or in each part separately. Part III may not be taken until five years of study have been completed.

M.D. and Ch.M.—Candidates for these degrees must have received the M.B. and Ch.B. at least two years previously. Students holding equivalent degrees of other approved universities may become candidates for the M.D. degree after two years' study in the university or clinical school of the university. The M.D. candidate submits for approval a dissertation covering original work, and Liverpool Graduates in Medicine who have been in practice for five years may be admitted to the degree by examinations. The M.Ch. candidate undergoes an examination. Other information concerning the diplomas of this university and its medical school will be found on page 434.

FELLOWSHIPS, SCHOLARSHIPS, AND EXHIBITIONS.

The university awards Fellowships annually to students of distinguished merit, as follows:

(1) John Rankin Fellowships in Anatomy; two, each of the value of £120, tenable for two years. (2) Ethel Boyce Fellowship in Physiology and Pathology, value £100 and tenable for one year, open to fully qualified students of either sex. (3) John W. Garrett Fellowship in Bacteriology, value £100 and tenable for one year. (4) Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year. (5) Helt Fellowships in Physiology and Pathology, two in number, value £100 each and tenable for one year. (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in Surgical Pathology, value £150 and tenable for one year. (8) University Fellowship, £100.

There are, in addition, scholarships and exhibitions open to medical students.

VICTORIA UNIVERSITY OF MANCHESTER.

This university grants the four ordinary degrees in medicine and surgery, M.B. and Ch.B. and M.D. and Ch.M.; a diploma and a degree (B.Sc.) in public health; a certificate in factory and in school hygiene; a diploma in psychological medicine; and a degree and diploma in dental surgery. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof; see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the five years' curriculum, one such year being subsequent to the passing of the first M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history; (4) English history; (5) two subjects at choice, one of which must be a language approved by the Joint Board, the other being elementary mechanics or physics, chemistry, geography, natural history, or botany. It is held in July and September.

PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. At all examinations the subjects, or groups of subjects, prescribed can be taken separately or together, as the candidate pleases. The first M.B. is divided into Part 1, inorganic chemistry and physics; Part 2, biology (including animal and vegetable morphology, physiology, and laboratory work); Part 3, elementary organic chemistry and biochemistry. The parts may be taken separately or together. At the second M.B. the candidate is examined in anatomy and physiology; at the third in pathology and pharmacology (including *materia medica* and practical pharmacy). The Final Examination is divided into two parts, which may be taken separately, and includes medicine, systematic and clinical, mental diseases, and diseases of children, surgery (systematic, clinical, and practical, with a separate paper on ophthalmology), obstetrics and gynaecology, preventive medicine, forensic medicine and toxicology.

M.D.—A candidate for this degree must be a bachelor of medicine of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself.

Ch.M.—A candidate must have held, since becoming Ch.B., and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery; Branch II obstetrics and gynaecology; Branch III ophthalmology; Branch IV otology, laryngology, and rhinology.

FEES.

The following fees are payable: Matriculation, £2; on re-admission, £1 10s. Each M.B. examination, £3 8s.; on re-admission, after failure, £3 3s. M.D., including the conferring of the degree, £15 15s. Ch.M., £6 6s. for the examination and £9 9s. for conferment of degree. Application for further information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF SHEFFIELD.

The degrees of this university (M.B., Ch.B., and M.D. and Ch.M.) and the diploma in public health are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose.

PROFESSIONAL EXAMINATIONS.

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 21 years by the day of graduation; that he has pursued the courses of study required by the university regulations during not less than five years subsequent to the date of his matriculation or exemption from matriculation; three of such years at least having been passed in the university, one at least being subsequent to the passing of the first examination. The following examinations must be passed in due order.

First Examination.—The subjects are chemistry, physics, and biology. The intermediate examination in science—chemistry, physics, and zoology—will, on payment of the required additional fee, be accepted instead of this examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology.

Second Examination.—The subjects are anatomy and physiology. The candidate must have completed the second year of professional study, must have passed the First Examination, and must have attended (1) lectures on anatomy, and dissections during three terms; (2) lectures on practical, experimental, and chemical physiology and histology during three terms.

Third Examination.—The subjects are pathology and pharmacology, anatomy and physiology. Candidates must have completed the fourth winter of medical study and the requisite courses in these subjects, including *post-mortem* clerkship for three months.

Final Examination.—The subjects are medicine (including public health, mental diseases, and diseases of children), surgery, and obstetrics (including gynaecology).

Candidates must have completed the fifth year of study and must satisfy the examiners in all subjects at the same examination.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.M.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution affording opportunity for the study of practical surgery. The examinations are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES.

The Charter and statutes of the University of Wales provide *inter alia* for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. is required to pursue a course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed as a student in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth; University College of Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; and University College, Swansea. He must also hold an Arts or Science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study pursued for a B.Sc. or B.A. degree may be counted as part of the courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year; study of physiology and anatomy must extend over at least two academic years, and cannot be commenced until all the preliminary courses have been completed; hence the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced, except in the case of pharmacology, until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in the earlier subjects are held at the end of each academic year, and in the subjects of the second section each July.

WELSH NATIONAL SCHOOL OF MEDICINE.

Students can complete the whole of their curriculum in the Welsh National School of Medicine, which is an integral part of the University College of South Wales and Monmouthshire, and qualify for the degrees of M.B., Ch.B. in the university.

The Committee of Management of the Examining Board of England of the Royal College of Physicians of London and the Royal College of Surgeons of England has recently made a report on the application from the Welsh National School of Medicine to be recognized for the complete curriculum. The Committee discussed various points arising out of the application with a deputation from the University of Wales, and expressed itself as generally satisfied with the provision made for teaching. The Royal Colleges have accordingly resolved:

That the Welsh National School of Medicine be recognized provisionally for the complete curriculum from October 1st, 1922, for one year, and that on such conditions as are fulfilled not later than January 1st, 1923, such recognition become permanent, namely:

1. The total number of beds, exclusive of cots, available for the teaching of medicine in King Edward VII. Hospital, Cardiff, shall not be less than 80.

2. Of these 80 beds, not less than 30 shall be allotted to the professor of the medical unit.

3. All physicians, surgeons, assistant physicians, assistant surgeons, and physicians and surgeons in charge of special departments at King Edward VII Hospital shall be recognized as teachers of the University of Wales.

4. Clinical clerkships and dresserships shall be provided for all students in professorial and non-professorial units.

5. Courses of instruction in all special departments required by the Regulations of the Examining Board in England shall be provided.

Further information may be obtained from the Registrar, the University Registry, Cathays Park, Cardiff.

English Medical Corporations.

THERE are three medical corporations in England—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the "Conjoint Board." Details concerning this body, its component Colleges, and the third licensing body here follow.

THE CONJOINT BOARD.

This body deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who satisfy it for the Licence and for the diploma of Membership respectively. The successful candidate is then entitled to register as L.R.C.P. Lond., M.R.C.S. Eng. It performs the same task in connexion with diplomas in State medicine, tropical diseases, ophthalmic medicine and surgery, and psychological medicine, jointly issued by the two Colleges in question. It obliges all candidates to pass one of a large number of examinations which it considers satisfactory, tests of general education, and thereafter to pass five years in professional study at a recognized medical school, allowing, however, six months to be spent at any institution which may be recognized by the Board as giving efficient education in chemistry and physics. A list of such institutions, as also of the tests accepted in regard to general education, can be obtained from the Secretary of the Board at the Examination Hall, Queen Square, Bloomsbury, W.C.1.

PROFESSIONAL EXAMINATIONS.

There are three examinations for the Conjoint diploma, or L.R.C.P., M.R.C.S., which are commonly known as First Conjoint, Second Conjoint, and Final.

First Conjoint.—This examination is in three parts: (1) Chemistry, (2) physics, (3) elementary biology. A candidate must present himself for examination in Parts 1 and 2 together until he has reached the required standard to pass in both, or in one of these parts, but he will not be allowed to pass in one part unless he obtains at the same time half the number of marks required to pass in the other part. A candidate may take Part 3 separately, or he may present himself for the whole examination at one time.

Before admission to any part the candidate must show that he has undergone certain courses of theoretical and practical instruction, but these courses need not be completed within one year, nor need they run concurrently, and they may be commenced or attended before the candidate passes the required preliminary examination in general education. A candidate referred in any part or parts will not be admitted to re-examination for three months. He must produce evidence of further instruction in the subjects in which he was referred. Those who are already graduates in medicine, or who have passed an examination in the same subjects before a university board for a degree in medicine, may obtain exemption from re-examination in those subjects at this examination.

Second Conjoint.—This examination is in two parts—namely, Part 1, anatomy and physiology; Part 2, materia medica and pharmacology. A candidate must have attended, at a recognized medical school, lectures on anatomy, physiology, and a course of practical physiology and histology, and have dissected for twelve months during the ordinary sessions. He must also attend three months' lectures or demonstrations in pharmacology, and receive instruction in practical pharmacy. Part 2 may be passed at the same time as Part 1 or before or after that part, provided

the conditions of admission to the whole examination have been fulfilled. The study of anatomy and physiology before passing in two of the three subjects of the first examination is not recognized. If rejected, a candidate before being admitted to re-examination must continue his studies at a recognized medical school for not less than three months.

Final Conjoint.—This examination consists of three parts: Part 1, medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health; Part 2, surgery, including pathology, surgical anatomy, and the use of surgical appliances; Part 3, midwifery and gynaecology. The examination may be passed at one time or in each part separately. Evidence of attendance at courses of instruction in the subjects of the three parts must be produced, and also of having conducted twenty labours. A candidate will be admissible to Parts 1, 2, and 3 of the Third or Final Examination at the expiration of two years (twenty-four months) from the date of passing the Second Examination, and on production of the required certificates of study, provided that the examination is not completed before the expiration of five years (five winter and five summer sessions) from the date of passing the Preliminary Examination. A rejected candidate must produce evidence of further instruction during at least three months.

Note.—New Regulations will come into force on January 1st, 1923, which will apply to all candidates who have not passed a recognized Preliminary Examination in general education before that date. Under these new Regulations candidates will be required to pass a Pre-Medical Examination in Chemistry and Physics, and to complete five years of professional study at a recognized medical school and hospital after passing such examination. The new Regulations will be obtainable from the Secretary in November next.

NOTE.—A person holding a Colonial, Indian, or foreign qualification which entitles him to practise in the country where such qualification has been obtained is, after a course of study and examination equivalent to those required by the Regulations of the two Royal Colleges, admissible to the Second and Third or Final Examinations without any interval. Members of an English, Scottish, or Irish University, or of certain conditions eligible for admission to the examination two years after passing at the First and Second Examinations of the Board. A member of an Indian, who sha of Dock First ar eligible after passing in the said subjects.

FEEs.

First examination, £10 10s. Re-examination in chemistry, £3 3s.; re-examination in physics, £2 2s.; re-examination in biology, £3 3s. Second examination, £10 10s. Re-examination in Part I, £6 6s.; re-examination in Part II, £3 3s. Third Examination, £21. Re-examination in Part I, medicine, £6 6s.; Part II, surgery, £6 6s.; diseases of women, £4 4s. Members of English universities, £5 5s. for first admission to the examination for the diplomas.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

This College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have passed the final examinations for the Licence, or those who are registered practitioners and graduates of a recognized university; in any case they must be persons over 25 years of age, who do not practise in partnership; dispenso medicines, or engage in trade. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce. Those under 40 are also examined in Latin, and either Greek, French, or German. The examination fee is £6 6s.; the Membership fee is £42, or the difference between that sum and what the candidate has already paid as a Licentiate. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, which may be passed, after the

third winter session; the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees.

Fees.—At first examination, £8 8s.; for re-examination, £5 5s. At second examination, £12 12s. Diploma fee for non-members, £10 10s.

The College also issues a diploma (L.D.S.) in dentistry.

SOCIETY OF APOTHECARIES OF LONDON.

This body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A. (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations:

Primary Examination.—This is divided into two parts, of which Part I includes elementary biology, chemistry, chemical physics, practical chemistry, pharmacy. Part II includes anatomy, physiology, and histology, and cannot be passed before the completion of twelve months' practical anatomy with demonstrations. Candidates will be excused any or all the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Final Examination.—This is divided into three parts. Part I includes clinical surgery, the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes clinical medicine: (a) The principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology; (b) forensic medicine, hygiene, theory and practice of vaccination and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances.

The fee for the primary examination is £5 5s.; for the final, £15 15s. The regulations and synopses relating to the several examinations, and other information, may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, E.C.4.

The Scottish Universities.

THERE are in Scotland four universities, each possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also diplomas in psychiatry and public health. As for public health, registrable degrees in this subject are granted by the Universities of Edinburgh and Glasgow, while diplomas in public health may be obtained from the Universities of St. Andrews and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts or Science (for degrees in pure science).

After January 1st, 1923, prospective medical students will also be required to pass a pre-registration examination in chemistry and physics.

PROFESSIONAL EDUCATION.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and in addition necessitate definite study for stated periods of diseases of children, of the larynx, ear and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the beginning of May to the middle of July.

PROFESSIONAL EXAMINATIONS.

The distinctive feature of the Scottish curriculum is that, though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics, and with anatomy and physiology at the end of the second. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that, when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with first or second class honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second, with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, forensic medicine and public health, and clinical gynaecology. The first three examinations are held three times a year; the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed an arts or science degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

THE HIGHER DEGREES.

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Services, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

FEES.

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £247, the separate examination fees included in this calculation being as follows:

	£	s.	d.
First Professional	9	9	0
Second Professional	7	7	0
Third Professional	6	6	0
Final	11	11	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £21, and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND.

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P. Edin., L.R.C.S. Edin., and L.R.F.P.S. Glasg. The Board requires all candidates to comply with the regulations of its own; but is prepared to accept in its place any of the other educational tests approved by the General Medical Council.

PROFESSIONAL CURRICULUM.

Subsequent to registration as a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held twice in Edinburgh and twice in Glasgow during the next period; it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology; the second with anatomy and physiology, including histology; the third with pathology and materia medica, including pharmacy; and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine; (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes; (3) midwifery and diseases of women and of newborn children; and, if it has not been passed previously, (4) medical jurisprudence and hygiene. Candidates may also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the

third examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own; but all candidates for the Conjoint licence must sit for the final examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

FEES.

It is estimated that the total cost of lectures and fees for the conjoint licence is about £152. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final £15. On re-entry for any of the first three examinations £3; and on re-entry for the Final, £5. If the re-entry is only in one or two subjects the fees are smaller.

Information concerning this Board should be sought either from Mr. D. L. Eadie, 49, Lauriston Place, Edinburgh, or from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THIS College has three grades—Licentiate, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday, except in September and October. Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, and in one further subject at choice. This may be either (a) one of the departments of medicine specially professed; (b) psychology; (c) general pathology and morbid anatomy; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) gynaecology; (h) diseases of children; or (i) tropical medicine. Licentiates of the College pay £21, others £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship the candidate must have been a member of the College for at least three years, and, if accepted, pays fees, including £25 stamp duty, amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THIS College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

Licence.

As an original qualification the Licence is only granted after fulfilment of the regulations of the Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

Fellowship.

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of their

profession subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (a) the principles and practice of surgery, including surgical anatomy, (b) clinical surgery, and (c) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology, and rhinology, gynaecology, obstetric surgery, anatomy, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials obtained specially for the purpose.

Licentiates of the College pay £35, and others £45. For further information application should be made to the Clerk of the College, Mr. D. L. Eadie, 49, Lauriston Place, Edinburgh.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s., and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. Special regulations are in force for medical practitioners who served in the late war. The Faculty can also elect four Fellows annually without previously submitting them to examination, providing they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age. Further information can be obtained from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

The Irish Universities.

THERE are three universities in Ireland, each with a medical faculty. These are the University of Dublin (usually known as Trinity College, Dublin), the Queen's University of Belfast, and the National University of Ireland. The two former teach students, examine them, and grant degrees; while the third is an academic body only, inasmuch as its practical work is divided among three constituent colleges, situated, one at Cork, another at Galway, and the third in Dublin. Information as to the arrangements for the education of medical students will be found in the section relating to Irish Medical Schools.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and a post-graduate diploma in public health. It also grants a post-graduate diploma in gynaecology and obstetrics, for which one year's study is required. The degrees are granted to those who, having passed the Professional Examination, have also graduated in arts.

PROFESSIONAL EXAMINATIONS.

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. At least three of the five years' medical curriculum must be pursued at the School of Physic of the university. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

Preliminary Scientific.—This covers (a) chemistry, (b) physics, (c) botany and zoology; the three divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (a) anatomy, physiology, organic chemistry, and histology;

(b) applied anatomy and applied physiology. The two parts may be taken separately or together.

Final Examination.—*Part I:* Hygiene and medical jurisprudence, pathology and bacteriology, materia medica, and therapeutics. *Part II:* (a) Midwifery and gynaecology, (b) medicine and mental diseases; (c) surgery in all branches including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the final examination cannot be completed before the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis and may also examine him *vis à vis* on other medical subjects of a more general nature.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing, and have been engaged in practice for two years.

M.A.O.—The candidate must be a B.A.O. of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Dental Degrees.—The University of Dublin gives two degrees in dental science—namely, B.Dent.Sc. and M.Dent.Sc. The course for the former has a minimum duration of four years; for the latter, five years.

Further information regarding courses of instruction, etc. may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY, BELFAST.

The degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health. The first three degrees mentioned serve as qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B.D.S. and M.D.S.) are conferred by the university and also a diploma in dental surgery (L.D.S.).

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) Inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology, and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) Pathology, (2) materia medica, pharmacology and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the first examination has been passed.

The Final Examination includes: (1) Medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year, but students invariably take both parts at the end of their course. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

THE HIGHER DEGREES.

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show

6. the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. 3. degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed will include (1) a written paper on the principles and ethics of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and a written paper and clinical or practical and viva voce examination on a subject chosen from the following list:—Human anatomy, including embryology, (b) physiology, (c) pathology, (d) pharmacology and therapeutics, sanitary science and public health, (f) forensic medicine and toxicology, (g) mental diseases. The regulations for degrees of M.Ch. and M.A.O. are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND.

The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their three years of study at one or other of them. Those years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. 10 candidates at each constituent college are examined created by the university, and a common standard of education is secured by all courses of instruction and the regulations governing them having to be approved by the Senate, after considering report thereon from the Board of Studies of the university. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as diplomas in Public Health, in Mental Diseases, and in Tropical Medicine.

Further information can be obtained on application to the registrar, National University of Ireland, Dublin.

The Irish Corporations.

THERE are three licensing bodies other than the Medical Faculties of the Universities, and in Dublin, just as in London; there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall. In Ireland, as in England, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

THE CONJOINT BOARD IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations, the first of which cannot be passed earlier than the end of the first winter session, nor the fourth before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of the recognized medical schools at home and abroad. The first and second examinations deal respectively with (a) anatomy and physiology, and (b) biology; and (c) anatomy, (d) chemistry and physics, and (e) pathology. All parts of these examinations, and (b) physiology and histology. All parts of these examinations, as also of the following one, which deals with (a) pathology, (b) materia medica, pharmacy, and therapeutics, (c) surgery, (d) public health and forensic medicine, may be taken separately. *Final Examination.*—This is divided into three divisions, which cannot be completed until at least four years have passed in medical studies other than those for the first examination, and five years at least since the beginning of the curriculum. The divisions are (a) medicine, including

including ophthalmic and operative surgery; (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the divisions (a), (b), or (c), provided he has completed his curriculum as far as concerns the division in which he presents himself.

Fees.—Preliminary Examination, £2 2s.; re-examination, £1 1s. First Professional Examination, £15 15s.; Second, £10 10s.; Third, £9 9s.; Final, £6 6s.; re-examination fee is £2 2s. for each division.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, 123, St. Stephen's Green, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College, and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of Royal Colleges of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College, irrespective of sex.

Fees.—For the Licence in Medicine, 15 guineas; Special Examination, £21; for the Licence in Midwifery, 8 guineas; Special Examination, 16 guineas. For the Membership, 20 guineas to a Licentiate of the College, 35 guineas to others; a special examination costs 10 guineas extra. The Fellowship, £35, in addition to stamp duty, £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildaro Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce; while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and to neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*; if, however, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Licence pay 5 guineas for examination, which sum, if they pass, is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND.

A DIPLOMA is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Two periods of dissection, each not less than six months, must be included, and twenty-seven months of hospital attendance, or its equivalent. Three professional examinations have to be passed; they are held three times a year. The Primary Examination deals with biology, physics, and chemistry, practical and theoretical; the Intermediate Examination is in practical anatomy and physiology, and histology and materia medica. A candidate who has passed tests in any of the subjects of these examinations before another licensing body is exempt from further examination in such subjects. The Intermediate Examination, Part II, consists of pathology, medical jurisprudence, and hygiene. The Final Examination deals with medicine, surgery, midwifery, and pharmacy. The Hall's own examination in all these subjects must be passed. Women candidates are eligible.

Fees.—Primary Examination, £10 10s.; Intermediate Examination, £10 10s.; Final Examination, £21; Final alone, when the others have been passed elsewhere, £26 5s.

Application for other information should be made to the Registrar, 95, Merrion Square, Dublin.

MEDICAL SCHOOLS AND COLLEGES.

LONDON.

INFORMATION as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge. Apart from these facts, the only point to which attention can usefully be directed here is that on personal inquiry and investigation reason may be found for regarding the teaching accommodation and general arrangements for students at some schools as superior to those at others.

CHARING CROSS HOSPITAL.

THIS school, with its hospital, is situated in the centre of London, and is easily accessible. Primary and intermediate students attend lectures and practical work at King's College. The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, materia medica, toxicology, public health, and research work. An Institute of Post-graduate Medicine and for research work. An Institute of Post-graduate Medicine and for research work. An Institute of Post-graduate Medicine and for research work.

Women students are admitted to the school and hospital upon the same terms and conditions as men, and after qualification are eligible for resident hospital appointments. A separate common room and a female attendant are provided, but beyond this no further distinction is made.

Fees.—An entrance fee of 10 guineas and 8 guineas is payable by full course and final course students respectively, and an annual fee of 35 guineas covers all other expenditure, with the exception of 7 guineas for vaccination, dispensing, and fever hospital attendance, which must be taken outside the hospital. Membership of the Students' Club is included in these fees.

Further information may be obtained on application to the Dean of the Medical School, Charing Cross Hospital, London, W.C.2.

GUY'S HOSPITAL.

The hospital contains 643 beds in constant occupation. Thirty-three beds are set apart for diseases of the eye, and 40 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There is a special ward of 32 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the orthopaedic department, the department for the treatment of diseases of

the genito-urinary system, and the children's department; there are also some special beds for the treatment of syphilis.

The residential college fronts the east gate of the hospital, providing accommodation for 60 resident students. This contains a dining hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in twenty minutes. The Gordon Museum of Pathology, the Wills Library, the Departments of Chemistry, Physics, Pathology, and Pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research and provide the full curriculum for a medical qualification. Special classes are held for the First and Second Examinations for medical degrees of the University of London and for the first F.R.C.S. Eng. Special teaching is provided to meet the requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house-surgeons, eight house-surgeons, two ophthalmic house-surgeons, and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, and ophthalmic house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, electricity, anaesthetics, dentistry, orthopaedics, vaccine, tuberculosis, and genito-urinary and venereal disease; clinical assistantships in the various special departments are open to post-graduates.

Scholarships, Prizes, etc.—The following scholarships in Arts and Science are awarded. A. Open Junior Scholarships: (1) An Arts Scholarship of the value of £100, (2) a Science Scholarship of the value of £100; these are awarded annually in September. (3) A War Memorial Scholarship of the value of £200, awarded alternately in Arts and Science. This scholarship is open every other year; the next award will be made in September, 1922, in Science. B. Confined Scholarship in Science: A Junior Science Scholarship of the value of £100 is offered for competition, annually in September, to candidates who have attended preliminary science classes at this school. Candidates for these scholarships (male students only) must be under 21 years of age on October 1st of the year of the competition. C. Open Senior Science Scholarships: (1) A War Memorial Scholarship of the value of £80, (2) an Open Scholarship of the value of £80; both of these are awarded annually in September. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency, £20, £15, £10; Hilton prize for Dissection, £5; Michael Harris prize for Anatomy, £10; Sands-Cox Scholarship for Physiology, £15 for three years; Wooldridge Memorial prize for Physiology, £10; Beane prize for Pathology, £34; Treasurer's gold medal in Medicine, Treasurer's gold medal in Surgery, and the Golding-Bird gold medal and scholarship for Bacteriology (£20), are awarded annually after competitive examination. The Gull Stewardship in Pathology of the value of £250 per annum, the Beane Scholarship in Materia Medica, of the annual value of about £50, and the Anderson Demonstratorship in Clinical Chemistry, value £150 per annum, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstratorship in Pathology of the value of £320 per annum, and the Hilda and John Griffiths Demonstratorship in Pathology, value £140 per annum, are awarded.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S.E.1.

KING'S COLLEGE HOSPITAL.

THE medical school of this hospital, which is situated at Denmark Hill, deals with the advanced or final subjects of the medical curriculum. The hospital was opened in 1913, and is the most modern and best equipped in England. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, and obstetric tutors. There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology and rhinology, dermatology, radiology, and physio-therapy. The laboratory and pathological department are specially noteworthy.

Appointments.—Fourteen resident medical and surgical officers are appointed half-yearly, as well as dressers and clerks in the wards, out-patient departments, *post-mortem* rooms, and special departments. Each of the special departments has several clinical assistants. There are three registrars and four tutors, all of whom receive salaries. The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also a common room.

Scholarships, etc.—At entrance: Arts Scholarship, £50; Science Scholarship, £50. At commencement of Final Studies: Anatomy and Physiology Scholarship, £50; Pathology and Pharmacology Scholarship, £50; two Bursary Yeo Scholarships, each £80 (for Oxford and Cambridge students); Senior Scholarship, £40; Todd Prize, Tanner Prize, Class Prizes and Medals.

Fees.—The composition fee is 93 guineas if paid in one sum. Entrance fee 10 guineas, includes membership of the Clubs and Societies Union.

The calendar of the school can be obtained on application to the Dean, H. Willoughby Lyle, M.D., F.R.C.S., or to the Secretary, S. C. Ranner, M.A., King's College Hospital, Denmark Hill, S.E.5.

THE LONDON HOSPITAL.

This hospital, with its medical college and dental school, is situated in the Mile End Road, E.1. The hospital contains 950 beds, and during 1921, 18,770 patients passed through the wards and 108,153 out-patients received treatment. Of the latter number, 32,036 received treatment in the departments for diseases of the ear, nose, throat, eye, skin, and teeth, and in the obstetric, orthopaedic, venereal, radiological, electro- and physio-therapeutic and inoculation departments. The number of major operations which were performed amounted to 7,466.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

The clinical units in medicine and surgery co-ordinate the teaching of their subjects in the hospital. The directors and their assistants give practical instruction in elementary clinical medicine and surgery to all students before they are allowed to enter the wards and out-patient department. Senior students are encouraged to work with the units. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staffs of the units.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. A course of post-graduate training is held in the work of school clinics for school medical officers (actual and intending) and others. Special entries can be made for the medical and surgical practice of the hospital. A residential hostel on hospital ground is provided for the convenience of students who wish to live near the wards and casualty departments. The athletic ground, of over thirteen acres, is at Highams Park, and is open to all members of the Clubs Union.

Appointments.—The salaried appointments open to past students of the Hospital are those of assistants to the clinical units, medical registrars, surgical registrars, obstetric registrar; medical, surgical, and obstetric tutors; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments, and in the Pathological Institute. There are appointed annually 4 resident accoucheurs, 14 resident house-physicians, and 24 resident house-surgeons, 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships, and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

Scholarships and Prizes.—The following is a list of scholarships and prizes: At Entrance: Price Scholarship in Science, £100; Price Scholarship in Anatomy and Physiology, open to students of Oxford and Cambridge Universities, £52 10s.; Entrance Scholarship in Science, £50; Epsom Scholarship, "Free Medical Education." After Entrance: Buxton Prize in Anatomy and Physio-

logy, £31 10s.; Lethcby Prizes in Organic Chemistry and Chemical Pathology, £25; Prizes in Clinical Medicine, Surgery, and Obstetrics and Gynaecology, £20 each; Duckworth Nelson Prize, in Practical Medicine and Surgery, £10; Hutchinson Prize in Clinical Surgery, £40; Sutton Prize in Pathology, £26; Sir Andrew Clark Prize in Clinical Medicine and Pathology, £26; Anderson Prizes in Elementary Clinical Medicine, £20; Dressers' Prizes, £40; Practical Anatomy Prizes, £10; Arnold Thompson Prize, in Medical and Surgical Diseases of Children, £15; Harold Fink Prize in Dental Surgery, £5 5s. The London Hospital Medical College and the Eliza Ann Alston Medical Research Funds amount to over £26,000.

Fees.—Entrance fee, 20 or 15 guineas, according to examinations passed; annual fee, 45 guineas.

Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.1.

THE MIDDLESEX HOSPITAL.

The school and hospital are in Mortimer Street, W., close to Oxford Circus, Goodgo Street, and Great Portland Street stations. There are prosperous athletic clubs and a gymnasium within the hospital precincts. The hospital contains over 450 beds, including a wing containing 92 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for cases of venereal disease and for diseases of children and of the skin and eye.

The medical school, which includes the Bland-Sutton Institute of Pathology and the cancer research laboratories, is completely equipped for teaching the entire medical curriculum, including the preliminary science course. The Bland-Sutton Institute, under the charge of the Professor of Pathology, contains large pathological and public health laboratories, and smaller rooms for original investigation as well as a pathological and anatomical museum. Bacteriological, chemical and microscopic examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Every facility is given for original research. The cancer research laboratories offer unrivalled opportunities for the study of this disease, in both its clinical and pathological aspects. Several valuable *in connexion with this connexion*. Students also receive electro-therapeutic and electro-cardiographic departments.

Appointments.—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two casualty medical and two casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination; six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. In the out-patient departments the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases; dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and *post-mortem* clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before holding in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the Medical, Surgical, Skin, Neurological, Ophthalmic, Throat and Ear, Odontological, Children's, and Electro-therapeutic Out-patient departments.

Scholarships.—There are three Entrance Scholarships, value £100, £50, and £25 respectively. An annual Entrance Scholarship, of the value of £50, is open to students of the universities of the United Kingdom who have completed the curriculum for, or passed the examinations in, anatomy and physiology. Students joining the school in the previous April are eligible. The Freer Lucas Scholarship is annually awarded on the nomination of the head master to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are numerous other valuable *scholarships*, prizes, and exhibitions open to students of the *scholarships*, viz Broadrip Scholarships, value £60 and £40, and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and *scholarships*, value £25; Hetley Clinical Prize, value £25; Leopo *scholarships*, value 11 guineas; and the Second Year's Exh.....

Fees.—(a) Preliminary Science students: For one year or less, £15. (b) Students who have completed the Preliminary Science course: Entrance fee, £15; four annual fees of £42. The annual fee for further attendance at the medical school, if a registrable qualification has not been obtained, is £21. Three-quarters, one-half, or one quarter of the last annual fee may, at the discretion of the School Council, be returned if the student obtains a registrable qualification within three, six, or nine months of the annual payment becoming due. (c) Oxford and Cambridge and other students who have completed the Intermediate course: Entrance fee, £10; two annual fees of £42; further annual fees as above.

Further information may be obtained from the Dean.

ST. BARTHOLOMEW'S HOSPITAL.

This institution fills one side of Smithfield and Giltspur Street, sharing with the Post Office buildings a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 757 beds. Extensive new buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library and the chemical, physical, biological, and physiological laboratories, and anatomical department, have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to a new extensive *post-mortem* room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. Within the precincts of the hospital also there is a residential college for a large number of students. The Students' Union owns, moreover, grounds of some 10 acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B., M.D. of the Universities of London, Oxford, and Cambridge, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.Ch.Cantab., M.S.Lond., and F.R.C.S.Eng. Special laboratory instruction for the D.P.H. of Cambridge, Oxford, Durham, and London is also given.

Clinical Units.—Special Clinical Units have been established in Medicine and Surgery, each under the charge of a professor and director who devotes the whole of his time to the purpose of hospital practice, teaching, and research. In each unit there are an assistant director and four assistants, for whom special laboratory accommodation is provided. The appointments of clerks and dressers are open to all students in these departments, and arrangements are made for all students to study in these units during a part of their clinical course.

Appointments.—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (Ophthalmic, Orthopaedic, Gynaecological, Children's, Laryngological, Aural, Dermatological, Venereal, Electrical, and Dental), and in the *post-mortem* room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical and in the special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "Junior" house-physicians and house-surgeons, and receive a salary of £80 a year. During their second six months they become "Senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident assistant anaesthetists are appointed each six months. Each is paid a salary at the rate of £80 per annum, and is provided with food and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

Scholarships.—Four entrance Scholarships are annually awarded after an examination held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) One scholarship, value £75, in not fewer than two and not more than three of the following subjects, Chemistry, Physics, Botany, Zoology, Physiology, and Anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £100, in not fewer than three of Chemistry, Physics, Botany, Zoology, and medical or surgical practice of any London medical school. (3) The entrance scholarship in Arts, of the value of £100, will be given in Latin and mathematics, with one other language—Greek, French, or German. (4) The Jeffreson Exhibition in Mathematics, Latin, and one other language—Greek, French, or German—of the value of £50. The value of the scholarships and prizes is over £900 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

ST. GEORGE'S HOSPITAL.

This school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centres of London University established at King's College and University College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited apartments, and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

Appointments.—Four house-physicians, four house surgeons, and two casualty officers are appointed every six months. The house officers receive salaries at the rate of £50 per annum, in addition to board and residence. The casualty officers are non-resident, and receive salaries at the rate of £200 per annum. After the student has held a house appointment, the following are among others open to him: Medical registrarship at £200 per annum; surgical registrarship at £200 per annum; assistant curatorship of the museum, £100 per annum; obstetric assistantship, resident, at £50 per annum; the post of resident anaesthetist at £100 per annum; the posts (2) of junior anaesthetist, each at £30 per annum.

Scholarships.—Two university entrance scholarships in anatomy and physiology (90 guineas and £70) are awarded at the commencement of each winter session. The William Brown Exhibition of the value of £135 per annum (tenable for two years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition of £49 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees.—First year, £35 15s.; second and third years, £36 15s. each. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £42. No entrance fee is payable by St. George's students who have studied at King's and University Colleges.

Further information may be obtained from the Dean of the Medical College.

ST. MARY'S HOSPITAL.

This hospital and medical school are situated close to Paddington Station (G.W.R.), having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 305 beds, and, by a scheme of affiliation, for teaching purposes, of the Paddington Infirmary, Paddington Green Children's Hospital, and Maida Vale Hospital for Nervous Diseases, the teaching facilities extend over 1,000 beds. The athletic ground (10 acres) is situated at Wembley, and can be reached in thirty minutes by a constant service of trains; a large pavilion has recently been erected.

Clinical Facilities.—Clinical Units in Medicine and Surgery were established in 1920, and have now been formally recognized by the University Grants Committee, St. Mary's being

one of the six medical schools in London which enjoy this privilege. Lying-in beds have been recently added, and provide special facilities for the teaching of Practical Midwifery.

Institute of Pathology and Research.—Students specially interested in pathology and bacteriology have singular advantages at St. Mary's. The Institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S. Three research scholarships of £200 each are awarded annually to students working in the departments of the Institute; and research beds are provided. Clerkships in Pathology and Bacteriology and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually.

Complete Curriculum.—The medical school provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Entrance Scholarships.—Five Scholarships (value £100, £52 10s., £52 10s., £50, £25) are awarded annually by competitive examination in September.

Fees.—Composition fee for entire course (51 years), £200 in one sum, or £210 by five annual instalments (clinical curriculum (2½ years), 90 guineas... by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas, with an entrance fee of 10 guineas.

ST. THOMAS'S HOSPITAL.

This school and hospital are situated in Lambeth, on the south bank of the Thames, facing the Houses of Parliament, and form one of the well-known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 1 p.m. The Students' Club premises contain a dining room and smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium. Good meals are obtainable at a moderate tariff. The Terrace affords facilities for exercise and recreation. The sports ground, of more than nine acres in extent, is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 632 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room; it is arranged also for lantern demonstrations. The maternity ward, containing 20 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for supplementary instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments.—All hospital appointments are open to students without charge. A resident assistant physician, a resident assistant surgeon, and a resident anaesthetist are appointed annually at a salary of £200 each per annum. Two hospital registrars, medical and surgical, at an annual salary of £250 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar, an ophthalmic registrar (at an annual salary of £50 each), and an orthopaedic registrar (unpaid) are appointed yearly. Ten resident casualty officers and anaesthetists (including two senior) are appointed every six months. Seven house-physicians (including two obstetric house-physicians, and one house-physician to the department of diseases of children) and eight house-surgeons (including two ophthalmic house-surgeons, one orthopaedic house-surgeon, and one house-surgeon to the ear, nose and throat department) are appointed every six months. Eight

clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Two research assistants (bacteriological and chemical) are paid £200 per annum each. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships.—There are five entrance Scholarships: Two in Arts, giving one year's free tuition; one of £150 and one of £60, in Chemistry, Physics, and Biology, for students who have not received instruction in Anatomy or Physiology; one of £100 in any two of the following subjects: Anatomy, Physiology, or Chemistry, for students who have completed their examinations in Anatomy and Physiology, for a medical degree in any of the universities of the United Kingdom or the colonies, and have not entered as clinical students in any London medical school. Valuable scholarships, prizes, and bursaries are open for competition throughout the whole career of a student. Louis Jenner Research Scholarship of the

Fees.—The annual fees are: For fees cover all tutorial classes, on infections fevers, pharmacy, and tions are permitted to attend which may be ascertained from the

Special courses of instruction are given for various examinations, and a register of lodgings is kept at the school. Further information may be obtained from the Medical Secretary of the School, St. Thomas's Hospital, Albert Embankment, S.E.1.

UNIVERSITY COLLEGE HOSPITAL.

The school, which forms part of the Corporation of University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine and clinical medicine, surgery and clinical surgery, midwifery and gynaecology, pathology, bacteriology, and chemical pathology and bacteriology. The school also includes departments of basic medicine, mental physiology and surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electro-therapeutics, and skiagraphy. The Hospital and School have acquired the National Dental Hospital and College as their Dental Department, thus providing every facility for the study of dental subjects. The Royal Ear Hospital, Dean Street, Soho, has also been amalgamated as the Ear, Nose, and Throat Department.

The school thus provides the final course of study for the degrees of the Universities of London, Oxford, Cambridge, Durham, and other British Universities, and for the diplomas of the Royal College of Physicians and Surgeons in Medicine and Dental Surgery, and the Licence of the Society of Apothecaries. Anatomical classes are also held in preparation for the examination for the degree of public health. Each department is also equipped for more advanced work, and provides facilities for research.

Whole-time directors of Medical and Surgical Units have recently been appointed, and are responsible for the systematic teaching of the principles of medicine and surgery. The teaching of practical medicine and surgery and of their special branches continues to be conducted by the honorary staff of the hospital.

The school has recently been the recipient of a large donation from the Rockefeller Foundation, which will enable it largely to increase its facilities for clinical and pathological study, and also to establish an Obstetrical Unit on similar lines to those of Medicine and Surgery.
